MINNESOTA STATE MEDICAL ASSOCIATION

'round the country all year 'round
reports published in the medical literature
keep telling **THE BENADRYL STORY:**

quick and economical relief in the majority of cases of allergy

Report after report corroborates BENADRYL's clinical efficacy. Study after study attests its value as an anti-histaminic agent in urticaria, penicillin and other drug sensitizations, food allergy, serum reactions, contact dermatitis, hay fever, erythema multiforme, pruritic skin lesions, angioneurotic edema, and vasomotor rhinitis.

BENADRYL HYDROCHLORIDE (diphenhydramine hydrochloride P. D. & Co.) is available in Kapseals® of 50 mg. each, in capsules of 25 mg. each, and as a palatable elixir containing 10 mg. in each teaspoonful. Descriptive literature on request.

Your Ability to Earn

is your

Greatest Asset

Life Insurance protects you in case you die too soon or live too long.

THE MASSACHUSETTS INDEMNITY GIVES YOU GUARANTEED MONTHLY INCOME IN CASE YOU ARE DISABLED.

Both Massachusetts Indemnity and Life Insurance policies require:

1. Full examination
2. Are incontestable after two years
3. Are guaranteed renewable
4. Provide waiver of premium
5. And have 31 days of grace

Don't make your policy part of the hazard of disability.

Protect your earning capacity with long term, noncancellable, incontestable disability insurance.

the far-reaching effects of Amniotin therapy

AMNIOTIN, Squibb complex of natural mixed estrogens, provides menopausal therapy *beyond the mere relief of vasomotor symptoms*. Amniotin does *more* than relieve climacteric flushes and sweating. The patient experiences a heightened feeling of well-being, improved strength and vigor, and "a greater sense of general relief, exclusive of the amelioration of hot flashes".[1] These are advantages attributed by many investigators to natural estrogen therapy.

Side-effects such as dizziness, headache, or nausea are rare with Amniotin therapy. Amniotin is well tolerated. It is easily metabolized by the body; readily detoxified by the liver.

Amniotin therapy is readily adaptable to each individual case. Whether symptoms are mild, moderate or severe, oral and intramuscular forms in a variety of potencies fulfill every need. Capsule suppositories are also available.

Amniotin

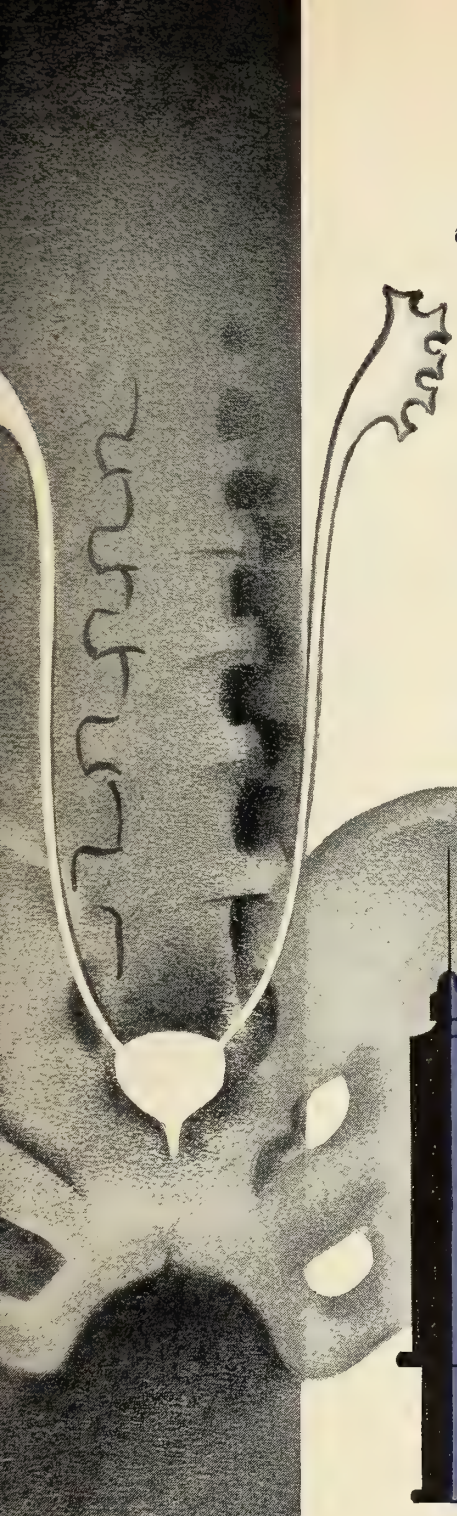
comprehensive protection with a **SINGLE INJECTION**

The use of Diphtheria and Tetanus Toxoids, Alum Precipitated, and Pertussis Vaccine Combined, has largely replaced the practice of repeated injections for immunization against specific infections. These combined antigens produce an immune titer equal to or greater than that effected by the antigen injected individually. The *simultaneous triple defense* provided by this comprehensive treatment greatly reduces the incidence of contagion in a community and makes possible a reduction of infant mortality rate.

Recommended for infants and pre-school age children, immunization consists of three 0.5 cc. subcutaneous injections at intervals of from four to six weeks.

Antigenic content of *H. pertussis* increased to 45,000 million organisms per immunizing treatment.



SUPPLIED:

Single Immunization package contains three ½ cc. Vials
Five Immunizations package contains three 2½ cc. Vials.

For medically sound reduction of overweight...

Benzedrine Sulfate—rational and accepted

Benzedrine Sulfate, by safely depressing the overweight patient's appetite, ordinarily curbs excessive eating. Lowered caloric intake and loss of weight naturally follow. Hence, Benzedrine Sulfate therapy is medically sound and highly effective.

Thyroid—irrational, potentially dangerous and widely condemned

In overweight, most authorities strongly condemn thyroid therapy as irrational and potentially dangerous, except in those rare instances when an accompanying hypothyroidism has been definitely demonstrated.

Benzedrine Sulfate—unlike thyroid—ordinarily, in the proper dosage, has no significant effect on the basal metabolic rate, blood pressure, or heart rate. Harris, Ivy and Searle,[1] after a comprehensive series of functional tests, conclude: "No evidence of deleterious effects of the drug (amphetamine sulfate) was observed."

[1]Harris, S. C.; Ivy, A. C., and Searle, L. M.: THE MECHANISM OF AMPHETAMINE-INDUCED LOSS OF WEIGHT: A Consideration of the Theory of Hunger and Appetite, J.A.M.A. 134:1468 (Aug. 23) 1947.

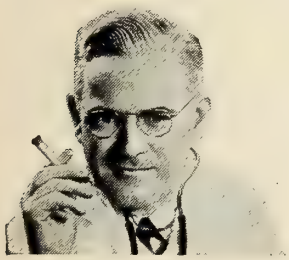
Experience is the Best Teacher



JOHN HUGHES BENNETT (1812-1875) proved it in histology

Bennett's experiences, gained by linking physiology with clinical medicine, led him to institute the practical study of histology, to recognize the medicinal value of cod liver oil, and to be the first to describe the blood condition leukemia — Bennett's disease.

R. J. Reynolds Tobacco Company, Winston-Salem, N. C.

Yes! And experience is the best teacher in smoking, too!

DURING the wartime cigarette shortage, people smoked many different brands—any brand they could get. And as they smoked—they naturally compared the different brands . . . for taste, for mildness, for coolness . . . for all-round smoking enjoyment. More and more smokers found from the experience of those comparisons that Camels suit them best.

Result? *More people are smoking Camels than ever before!*

According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

Three nationally known independent research organizations asked 113,597 doctors — in every branch of medicine — to name the cigarette they smoked. *More doctors named Camel than any other brand.*

PICTURE OF how B. J. Bender became a nutritive failure....

Bender is but one of the great American army of chair-warmers, shining examples of the need for two-pants suits. Exercise? They lie down until the thought of it passes. Appetite? They seek the bizarre in food to goad their tired taste buds. Result? In too many cases, sub-clinical vitamin deficiency—a condition in which the sedentary worker has a host of companions in nutritional crime: the food faddists, chronic dieters, excessive smokers, alcoholics and many others. Dietary reform is the physician's first thought, of course—vitamin supplementation usually the second. And the vitamin preparation specified very often carries the "ABBOTT" name. There is a wide variety of vitamin preparations available in the complete Abbott line . . . for oral and parenteral use . . . for almost any patient's needs, age or taste. If you are not already familiar with Abbott's dependable vitamin products, they are worth your investigation—and trial. ABBOTT LABORATORIES, NORTH CHICAGO, ILLINOIS

TO THE PHYSICIAN WHO SMOKES A PIPE: We suggest an unusually fine new blend—COUNTRY DOCTOR PIPE MIXTURE. Made by the same process as used in the manufacture of Philip Morris Cigarettes.

PRIVINE hydrochloride, 0.05 per cent, is sufficiently potent to produce long-lasting relief in the average case of nasal congestion in patients of all ages. It is therefore the Privine preparation of choice for regular prescription purposes.

Privine hydrochloride, 0.1 per cent, fills the need for an agent which will produce the intense vasoconstriction frequently necessary for adequate visualization and for pre- and post-operative shrinkage. It is therefore the Privine preparation of choice for direct use in the office or hospital.

When properly administered, Privine hydrochloride induces prolonged vasoconstriction with relative freedom from local or general side effects. Three drops will usually produce nasal decongestion lasting 3–6 hours. Overdosage should be avoided.

Issued: 0.05%, bottles of 1 fl. oz. and 16 fl. ozs. • Jelly, 0.05%, tubes of 20 Gm.

"Ain't that something? *My* muscles aren't flabby fat—'cause (thanks to you) I have plenty of protein in my *Biolac*."

In fact, BIOLAC supplies among other essential nutrients the valuable proteins of milk (and thus the essential amino acids for sound structural development)—at a significantly higher level than human milk. By homogenization and heat treatment, curd size and tension are reduced for digestibility, and proteins are rendered desirably hypoallergenic. • BIOLAC is a *complete food* (when vitamin C is added). Its fat content is adjusted to a readily assimilable level, and its added lactose contributes to the formation of natural, soft stools. Mothers appreciate BIOLAC because of its safety and simplicity.

The Book of Life
. . . on one page

"Each person in the world creates a Book of Life. This book starts with birth and ends with death . . . has many pages for some and is but a few pages in length for others."[1]

A single page tells the life story of those infants who die within the first 30 days after birth. It is during this fatal first month that 62.1% of all infant mortality occurs—an increase of almost 10% in the past 20 years. There is urgent need then to utilize every advantage science offers in eliminating the hazards of neonatal life. A good start on the right feeding can do much to minimize the gastrointestinal hazards of excessive fermentation, upset digestion and diarrhea.

'Dexin' has proved an excellent "first carbohydrate" because of its high dextrin content. It (1) resists fermentation by the usual intestinal organisms; (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds. 'Dexin' *does* make a difference.

EXCELLENT SUPPORT for the

PENDULOUS ABDOMEN

Patient with pendulous abdomen (skeleton indrawn).

Same patient after application of support (skeleton indrawn).

CAMP

Clinicians are calling attention to the ill effects of the pendulous abdomen more frequently than formerly.

Research discloses that the increased weight of the abdomen, carrying the center of gravity forward, puts strain on muscles of back and feet; that ultimately round shoulders and increased cervical and lumbar curves develop; that the diaphragm and abdominal viscera lie on a lower plane than normally; that eventually respiratory and circulatory symptoms appear.

S. H. Camp & Company, recognizing this proportionate irregularity and the frequency of its occurrence, has made supports for many years for these obese persons and for those in whom the obesity is largely confined to the abdomen.

Camp surgical fitters are taught to fit patients with pendulous abdomen in the reclining position; thus the intestines are redistributed to the sides and back of the abdomen and the support will hold them there.

The Camp Support illustrated is especially efficient in holding the viscera in their redistributed position by reason of the support given to the pelvis.

FOLLOW-UP DIAGNOSIS ON PATIENTS WITH X-RAY LESIONS

With Special Emphasis on Tuberculosis

WILLIAM ROEMMICH, M.D.

S.A. Surgeon, U. S. Public Health Service
Minneapolis, Minnesota

OF the 301,513 examinations in the mass chest x-ray survey conducted in Minneapolis during the summer of 1947, the x-ray interpretation in 3,791 instances was tuberculosis.* If sanatorium admissions were not carefully regulated, application might be made by part or all of these patients for admission to the sanatorium. That, of course, would be impossible, even under such favorable sanatorium conditions as exist in Minneapolis and Hennepin County. Fortunately, only a small portion of patients found to have x-ray lesions suspicious of tuberculosis need sanatorium admission. Therefore, we must devise some follow-up diagnostic procedure which will protect the community against infectious patients, conserve hospital resources, and give maximum benefit to the individual.

Since the start of the mass chest x-ray survey as a case-finding method in tuberculosis, many symptomless patients have gone to their physicians. As our experience with these surveys increases, we are repeatedly impressed with the incidence of other pulmonary and thoracic lesions. We are repeatedly impressed also with the fact that everything which looks like tuberculosis roentgenologically is not tuberculosis clinically. The variety of lesions increases as our diagnostic efforts increase. We know that the differential diagnosis of these intrathoracic lesions, although extremely difficult, becomes a very fascinating and rewarding endeavor. None of them is simple. Even the specialist will need to call freely on the special techniques of his colleagues.

With patients referred from the mass x-ray survey, the physician is faced with an experience which is just a little different from that of his daily office routine. He must urge special diagnostic studies upon a patient who is symptomless. A presenting complaint is " a spot on my lung." The extra effort needed to sell and make an early diagnosis, as compared to that needed when a patient has symptoms or is in the more obvious phases of disease, will be rewarded by a more favorable clinical response.

Perhaps the most prevalent single disease which will need to be considered in the differential diagnosis of lung lesions will be tuberculosis. I should like to limit my discussion largely to that phase of the diagnostic problem. The epidemiological significance of tuberculosis to the community places a grave responsibility on the physician not to rule out tuberculosis or call it inactive without adequate study in addition to the x-ray. The tremendous economic and social implications to the patient and his family make it imperative that the physician exhaust every resource to be absolutely certain that his diagnosis is based whenever possible on bacteriological evidence.

When a patient goes to a physician from a mass x-ray survey, he has at least a miniature film

---

Read at the annual meeting of The American College of Chest Physicians held in conjunction with the annual meeting of the Minnesota State Medical Association, Duluth Minnesota, July 1, 1947.

Dr. Roemmich is Acting Tuberculosis Control Officer of the Minneapolis City Health Department.

*The figures quoted herein bring the report up to date as at close of survey October 15, 1947.

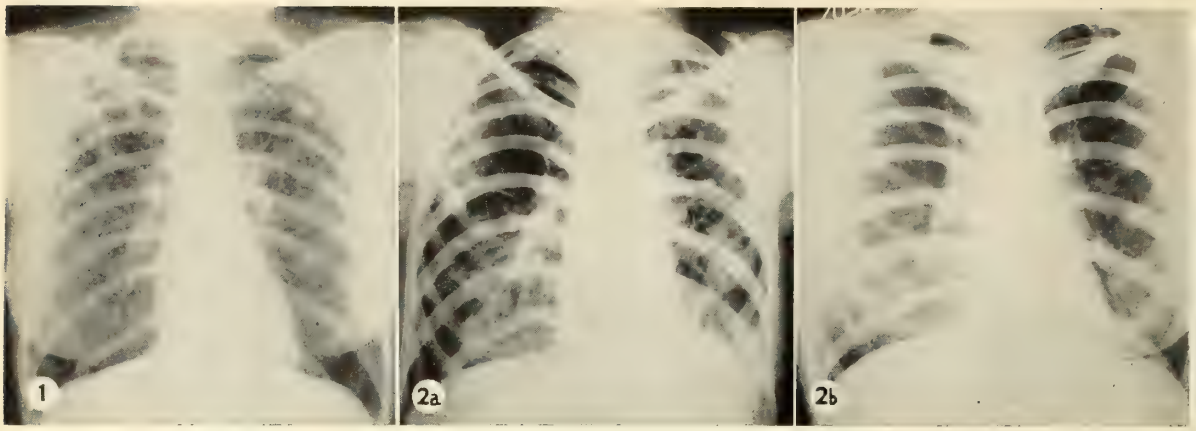

Fig. 1. *Case 1.* H. N., a woman, aged thirty-six, was diagnosed as having definite bilateral fibroid and exudative pulmonary tuberculosis. The diagnosis was made by x-ray only. After four months of intensive study in a sanatorium, tuberculosis was definitely ruled out. The final diagnosis was pulmonary fibrosis.

Fig. 2. *Case 2.* (a) O. R., a woman, aged twenty-eight, was diagnosed as having far advanced pulmonary tuberculosis over the left lung and the middle of the right lung, with bilateral cavitation. The diagnosis was made by x-ray only. (b) After eight months of intensive study, the lesions gradually disappeared. The final diagnosis was subacute Loeffler's syndrome.

reading. Upon this evidence a diagnosis should never be based. In Minneapolis, and in some other projects as well, he also will have had a 14 by 17-inch film. The diagnosis of tuberculosis from x-ray alone is never permissible. To make it in exceptional cases, on a little additional evidence in a very isolated rural area, is understandable. To make it on x-ray evidence only, where laboratory and other special techniques are available, is inexcusable.

What are some of the diagnostic procedures which should be used in the differential diagnosis of tuberculosis? We cannot discuss them all. I would like to suggest four, all four of which can be used by a general practitioner or chest specialist: (1) x-ray, (2) bacteriological studies, (3) tuberculin test, and (4) history and physical examination.

The x-ray is an economical tool in tuberculosis case finding. It is a most useful aid in making a diagnosis of tuberculosis. For follow-up and treatment it is essential. I can think of no diagnostic aid which in recent years has been subjected to such a large scale use—one which has been cross-examined by a skeptical public and not a few in our professional groups. Yet it remains as one of the objective and valuable diagnostic aids. My discussion of its use in the differential diagnosis of tuberculosis is not intended to discredit x-ray but to urge an even wider application with a more extensive use of complementary diagnostic aids. I shall present three cases, two of which were obtained through the courtesy of Dr. Sumner S. Cohen at Glen Lake Sanatorium. These cases illustrate how the x-ray can be used to aid the making of a diagnosis. At the same time they illustrate how hazardous it can be to use x-ray alone. These are not isolated cases; many others might be cited.

Case Reports

Case 1.—H. N., (No. 9752) a thirty-six-year-old woman, went to see her physician on August 20, 1946, complaining of slightly swollen ankles of twenty months' duration. At this time there were no symptoms referable to her lungs. As part of a general physical examination, her physician requested a chest x-ray. The roentgenologist reported definite pulmonary tuberculosis. Application was made to Glen Lake Sanatorium, and within eight days the patient was admitted. There was no history of exposure. Temperature and pulse were normal and remained so throughout her sanatorium stay. The admitting physician reported slight increased whispered voice sounds in both apices. Admission x-rays (Fig. 1) were interpreted by an experienced roentgenologist as follows: "Bilateral fibroid and exudative pulmonary tuberculosis extending to the second right anterior interspace, and to the second left anterior interspace with questionable cavitation in the right apex."

Several x-rays during her sanatorium stay showed no change. Repeated tuberculin tests using the two National Tuberculosis Association standard test doses of PPD, and four doses of O.T. ranging from .1 to 10 mg., were negative. Sputum was absent, and four gastric washings were negative for tubercle bacilli. Other laboratory studies revealed no abnormalties. After four months of study the patient was discharged with a diagnosis of chronic pulmonary fibrosis of unknown etiology.

We must recognize that the exact etiology in this case was never demonstrated. However, I

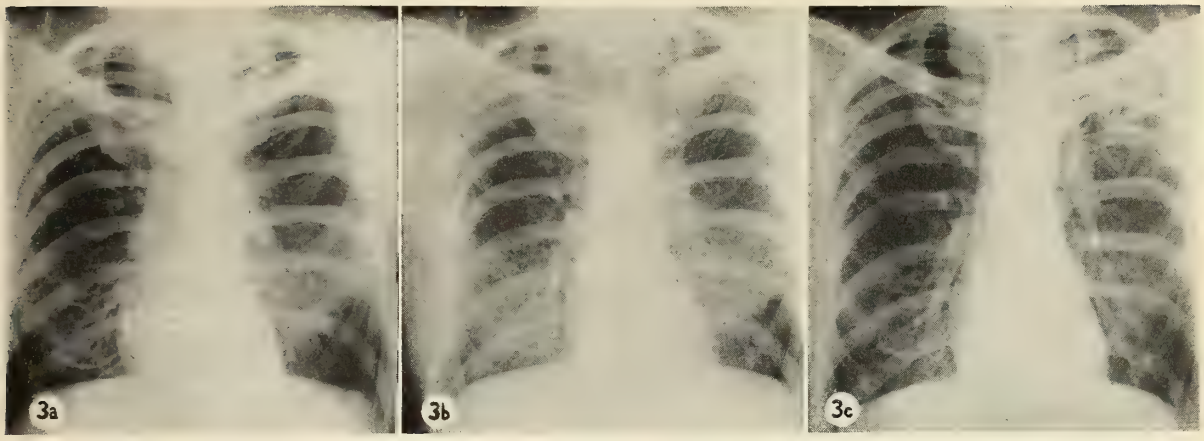

Fig. 3. *Case 3.* (a) H. J., a man, aged fifty-three, was diagnosed in December, 1941, as having "healed primary childhood tuberculosis." The diagnosis was made by x-ray only. (b) An x-ray taken in March, 1943, was interpreted as "no change, healed primary tuberculosis." (c) In March, 1947, fatigue, expectoration and chest pain appeared. The diagnosis by x-ray was reactivation of childhood tuberculosis. Ten sputum smears were negative for acid-fast bacilli, but the first and all subsequent sputum and gastric cultures were positive for tubercle bacilli.

believe the following questions are open for discussion: Could this study have been carried out in the private physician's or specialist's office? Should the patient have been given the original diagnosis with its emotional, social, economic and epidemiological implications?

Case 2.—O. R., (No. 7028) a twenty-eight-year-old woman, first noticed a persistent, dry cough in December, 1937. She was pregnant at the time, and in March, 1938, was delivered of a normal infant. At her routine postpartum examination she again complained of a cough. Her physician made a diagnosis of bronchitis and treated her for it without improvement. A single tuberculin test in May, 1938, was negative. In June, 1938, the cough increased. She developed expectoration, anorexia, weight loss, malaise. A chest x-ray was interpreted "pulmonary tuberculosis." A second tuberculin test was positive. One sputum examination was negative.

She was admitted to Glen Lake Sanatorium. There was no history of exposure. Her husband and four children were examined for tuberculosis. Additional history revealed attacks of coughing and wheezing prior to the present illness. Her temperature reached a high of 102° and her pulse 110. The physician's examination at the time of her admission revealed impaired resonance in the upper half of the right lung and over the left lung field. Bronchovesicular breath sounds and increased whispered voice sounds were heard over the left lung field. In addition râles were heard over the fourth and eighth dorsal interspaces posteriorly on the left. An x-ray (Fig. 2a) was interpreted as follows: "Far advanced pulmonary tuberculosis over the entire left lung and middle part of the right lung with bilateral cavitation."

Tuberculin tests done with PPD were negative to all strengths. Fifteen sputum smear examinations were negative. Guinea pig inoculation of sputum was negative, as were stool and gastric cultures. Blood hemoglobin was 78 per cent; the white blood cell count was 12,400, with 54 per cent polymorphonuclear neutrophiles, 28 per cent lymphocytes, 5 per cent monocytes, and 17.5 per cent eosinophiles. Subsequent blood examinations revealed a variation of eosinophiles from 7.5 to 16 per cent. Serial x-rays showed rapid improvement (Fig. 2b). She was discharged in November, 1938, with a final diagnosis of allergic pneumonitis or "subacute Loeffler's syndrome."

The questions which were asked at the end of the previous case might well be repeated here.

Case 3.—H. J., a fifty-three-year-old man, was laid off from his job in a foundry in 1941. He had a "spot on his lung." He went to his private physician who made an x-ray and told him he had "healed childhood tuberculosis" (Fig. 3a). He could not regain his job at the foundry, so he obtained a job as a painter and worked until March, 1943, when a second x-ray was taken (Fig. 3b) with an interpretation of "no change, healed childhood tuberculosis."

In March, 1947, he had chest pains and expectoration. He felt very tired. He returned to the same physician for a third x-ray (Fig. 3c) which was interpreted as "reactivation of childhood tuberculosis." Application was made to the sanatorium, but the patient refused the physician's advice and went to a second physician. There he was given a diagnosis of far advanced tuberculosis. No sputum examinations were made.

He was referred to the out-patient department for study. Ten sputum smears over a two-week period were all negative. On April 15 at his first clinic appointment, a gastric wash was done and a second sputum smear was made. Both the sputum and the gastric washing were cultured. All subsequent gastric washings and sputa were cultured. On May 27 the first sputum and gastric cultures were both reported positive for tubercle bacilli. He was admitted to the sanatorium for treatment.

One might ask the questions: "Should a bacteriological study have been done in 1941?" "What would have been the result?" "If repeated in 1943, what would have been the result?" "Should the patient have gone from December, 1943, to March, 1947, without follow-up studies?" "Should we ever be satisfied when a smear is negative?" This patient had fifteen smears; of these the first two cultures were positive within four weeks.

The x-ray is a valuable tool in the diagnosis of tuberculosis. Unless, however, it is complemented by clinical and other laboratory studies, it may be hazardous to the individual and the community. I believe Dr. Rigler expresses a somewhat similar opinion in his handbook on *The Chest*. "Next to positive sputum characteristics, x-ray findings are the most definite evidence of the presence of pulmonary tuberculosis. X-ray signs of pulmonary tuberculosis do not necessarily indicate activity or quiescence of a lesion. In some cases the activity can be determined, but in many it is impossible to decide on the stability of a lesion unless repeated studies are made." As our experience with mass radiography increases, and as more and more competent laboratories intensify their search for tubercle bacilli, we realize that a lesion may be stable on x-ray for one year or more and still yield positive culture and other laboratory and clinical evidence of activity.

I would like to close the discussion on x-ray as a diagnostic technique with a quotation by Dr. J. A. Myers from *The Evolution of Tuberculosis—1921 to 1941*. "We must remember that we are inspecting only shadows of gross pathology and that shadows of tuberculous lesions may appear identical with those of other diseases that attack the lungs. Therefore, we have long since discontinued attempts to make so-called x-ray diagnoses, as it is a physical impossibility to determine whether a given shadow represents disease produced by tubercle bacilli or by any one of several micro-organisms, as well as by malignancy."

If only one criterion must be used to make a diagnosis of tuberculosis, the physician can do no better than to use bacteriological evidence. This is difficult, time-consuming, and not too satisfying to both physician and patient, who live in an age of speed. However, if one has available a competent laboratory, this method will be the most accurate. It will conserve community resources; it will provide the information needed for modern treatment and intelligent epidemiological control.

TABLE I. POSITIVE GASTRIC WASH VERSUS POSITIVE SPUTUM

Type of Patient	Number and Per Cent of Patients	Number and Per Cent of Examinations	Number and Per Cent Positive
No sputum	71 (15.3)	401 (14.0)	211 (52.6)
Negative sputum	111 (23.9)	783 (27.3)	314 (40.2)
Positive sputum	282 (60.8)	1682 (58.7)	746 (44.3)

Feld, in Am. Rev. Tuberc.: 7.5 per cent of positive gastrics become sputum positive within six months.

What can we expect from bacteriological diagnosis with a good laboratory? What studies should the physician request? How should these be integrated with the other diagnostic studies on his patient?

Feld studied intensively 868 adults admitted to the sanatorium with x-ray diagnosis of tuberculosis. In 464 of them, he was able to make a bacteriological diagnosis. He believes that he obtained bacteriological evidence on all patients with active tuberculosis. He performed from one to thirty bacteriological studies per patient depending on clinical indications. He states that 60 per cent can be diagnosed by sputum cultures alone, 24 per cent have a negative sputum but become positive with gastric culture, and 15 per cent have no sputum but gastric culture is positive (Table I).

There is some question about the 23 per cent with negative sputum and positive gastric culture. Hilleboe and Holm suggest that in the presence of sputum a gastric culture is not necessary. Feld's figure, 24 per cent negative sputum and positive gastric culture, would be smaller, I believe, if the clinician made sure that sputum came from the lungs and not from the sinuses. If there is doubt in the clinician's mind as to source of sputum, a gastric wash should be requested. A gastric wash is indispensable in children.

The physician may ask immediately, "How many sputum and gastric studies shall I do before I decide the patient is inactive or at least sputum-negative?" Serial x-ray will help in deciding whether a lesion is progressing or regressing. If there is progression and, especially in the presence of cavity, expectoration, and if continued sputum cultures in competent laboratories re-

TABLE II. STUDY OF CONSECUTIVE ASPIRATIONS

Aspirations	Number of Patients	Per Cent Positive
1	292	71.1
2	378	92.0
3	395	96.1
4	406	98.8
5	411	100.0

main negative, the physician must intensify his study for a non-tuberculous etiology.

Pinner says, "I have found it a practical working rule but not an iron-clad law to state that a patient with more than a minimal lesion, with evidence of activity and with reasonable amount of sputum, has probably not pulmonary tuberculosis if, on complete studies of frequent sputum and gastric samples, tubercle bacilli cannot be demonstrated."

If there is no sputum, what can we expect from gastric culture? Feld again gives some practical suggestions as to what may be expected from a gastric lavage. He found that one gastric aspiration yielded 71 per cent of those which would ultimately be positive, a second, 92 per cent, and so on, until a fifth would yield 100 per cent. (Table II). Unfortunately, he does not give a time interval between studies.

These studies agree basically with very intensive studies by Dr. Holm and his co-workers of Denmark. Dr. Holm gives a little additional information in a personal communication, from which I quote: "A smear will reveal about 20 per cent bacteriologically positive cases of tuberculosis, sputum cultures an additional 40 per cent, gastric cultures the last 40 per cent."

These figures give some idea of what has been done in competent laboratories. What can be done in each physician's laboratory will depend on the number of culture tubes used per specimen, the type of media used, the care with which culture material is prepared for culture, the care with which it is collected, and, as Glen Lake repeatedly points out, how promptly it is sent to the laboratory. By no means of least importance is the experience of the bacteriologist in culturing tubercle bacilli. This list of variables does not exhaust the factors which must be considered in determining dependability of culture work in tuberculosis.

The tuberculin test is another diagnostic aid in the differential diagnosis of tuberculosis. There is no test in the field of medicine that has been more extensively used and the results so carefully checked by post-mortem examination as the tuberculin test.

I would like to discuss some significant aspects of tuberculin sensitivity. I will refer specifically to Florence Siebert's preparation of PPD at the Phipps Institute. However, in its application as a diagnostic tool, the principles apply as well to intracutaneous testing with other PPD preparations and accepted preparations of Old Tuberculin. Intensive studies with this specific preparation probably represent the general pattern of tuberculin sensitivity.

It is evident that the quantitative titration of tuberculin sensitivity by the use of different concentrations yields information which throws considerable light on the diagnostic interpretation of the reaction. When the tuberculin sensitivity of each individual making up a population group is known, it is possible to construct a curve of tuberculin sensitivity for that group. When the same tuberculin solution and testing techniques are used throughout, it is possible to compare all curves of tuberculin sensitivity of various population groups. Such studies have been carried out by the U. S. Public Health Service and others. From such studies it is apparent that almost all persons tested react to tuberculin if large enough doses are injected and that certain persons react to very small doses of tuberculin. In the main, those groups who react to large doses of tuberculin only are among those with non-contact histories. Conversely, the majority of those who react to very small doses either have tuberculosis or a history of contact with it. Thus the non-contact group is relatively insensitive to tuberculin, while the contact group is highly sensitive.

Dr. Palmer points out that the sensitivity curves of a group, all of whose members have a history of contact or actual tuberculosis, differ markedly from those having no contact history. The difference is primarily that there is a greater percentage of reactors to smaller test doses. It is significant that not all children, even though proven contacts of open tuberculosis, are reactors. In two large groups tested, only 79 and 76 per cent reacted. Three possible explanations of this failure of persons with a history of contact to react to small doses of tuberculin must be considered.

1. These persons have been infected with the tubercle bacilli and have not yet become hypersensitive. Dr. J. A. Myers and his staff at the

Lymanhurst Clinic in Minneapolis showed that it takes from three to seven weeks for sensitivity to develop to a degree detectable by the tuberculin test. Having once become hypersensitive to tuberculin, they have subsequently become anergic.

2. Although they had lived in contact with open tuberculosis, they have not been infected.

3. Contact may have taken place with inactive tuberculosis.

The exact significance of skin reactions which are obtained only through large doses of tuberculin is not clear. There are reasons, however, which make it appear likely that these reactions are not specific, or in other words, they are not due to infection with the tubercle bacillus. In the first place, since almost everyone reacts if a large enough dose is used, it would have to be assumed that almost all persons tested have been infected with tubercle bacillus. Such an assumption seems unwarranted. In the second place, the character of the reactions to the larger doses of tuberculin is less stable over a period of time than that of the reactions to the smaller doses. It appears likely, therefore, that reactions occurring with large doses of tuberculin are not specific. This may be even more true when O.T. is used, which has, in addition to protein, a polysaccharide and nucleic acid constituent. It becomes important, therefore, to determine if possible at what dose of tuberculin the nonspecific character becomes evident. The U. S. Public Health Service is now recommending a one-dose technique using .0001 mg. PPD. As you will see later, with this as a first test dose, very little tuberculosis will be missed by omitting the second test dose. Dr. Palmer believes that the one test dose will pick up all significant tuberculosis and will not exclude significant tuberculosis. If we could eliminate a second dose and lose very little in diagnostic value, it would be very advantageous in case finding and clinic procedures. This suggestion needs careful clinical evaluation.

In Dr. Palmer's experience with over 500 cases of tuberculosis, more than 99 per cent reacted to .0001 mg. PPD. This dose is five times more concentrated than the N.T.A. first testing dose. Similar findings are reported by Long on 609 tuberculosis cases at the Phipps Institute. He reported that 94 per cent of the white and 96 per cent of the colored tuberculosis patients reacted to first testing strength of the PPD or O.T. After larger doses are used it should be with the realization that they may invoke nonspecific reactions and that such reactions occur with increasing frequency as the dosage is increased (Fig. 4).

What is a non-reactor, and what is a reactor? At the present time the N.T.A. is recommending the two-dose method of tuberculin testing. The first dose is .00002 mg. of PPD, and if the person is a non-reactor, a second dose of .005 mg. of PPD is given. The test should be read preferably at the end of a seventy-two-hour period but can be read in forty-eight hours. The reaction is indicated by an area of edema in the skin at the site of administration. This area should be at least 5 mm. in diameter for the first test dose, and 10 mm. for the second. In interpreting the tuberculin test, it is far better to use the sense of touch than the sense of sight.

I should like to summarize the use of the tuberculin test in diagnosis as follows: The tuberculin test, if properly used, will tell whether infection has taken place. If it is applied repeatedly, and if the activity of the product has been established, a non-reactor either does not have tuberculosis, is in the preallergic or the terminal stages of disease, or has lost his sensitivity. In the latter case there are no living organisms left in the body. If an x-ray pulmonary lesion is present in a non-reactor at the end of eight weeks, the lesion should be considered non-tuberculous.

The fourth and last diagnostic aid which I should like to discuss briefly is the history and physical examination. It perhaps is the oldest of the four diagnostic techniques discussed today. It has been discredited by some recently. They have suggested throwing the stethoscope away; early tuberculosis is symptomless and signless. That early tuberculosis is symptomless and signless in a majority of instances is very true. If we knew that patients who come to us from mass surveys had tuberculosis, we could throw away not only the stethoscope but all other diagnostic aids. But we don't know what these patients have. We don't know they are signless and the only way to find out is to do a physical examination and find out. In the differential diagnosis of tuberculosis there are many diseases which look like tuberculosis roentgenogically but actually may be other infections or malignancies which do cause physical findings, such as palpable nodes and fever. A rectal examination or abdominal palpation may reveal the primary focus of what looks like tuberculosis in the chest. A history of significant

contact with an open case, closed case, or terminal case, if present, strengthens the evidence for tuberculosis.

The history especially has far-reaching diagplosive implications. The chips are all down; the patient holds low cards. If the patient has tuberculosis, then, according to Plunkett, who has made a study of costs, the physician is about to

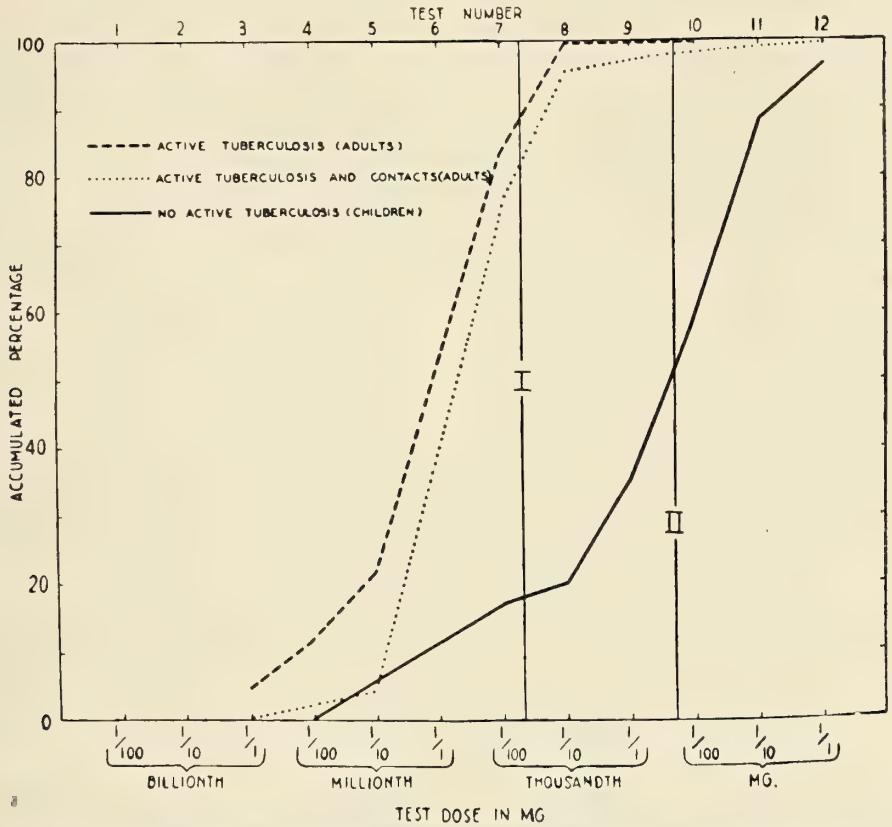

Fig. 4. Accumulated percentage of positive reactors to various test doses of PPD among 468 adults with active tuberculosis and 553 orphanage children with no apparent active tuberculosis. The vertical markings I and II represent the approximate levels of the first (0.00002 mg.) and second (0.005 mg.) strength doses of PPD as usually recommended.

nostic value and cannot be too detailed. No matter how diplomatic the letter which referred the patient from the mass survey to the physician, many patients are frightened at first. Later, after the first shock of "something wrong with my lungs" has been dissipated, they will throw up a protective barrier of "I'm not sick," or "I've never felt better in my life." They are only too eager to hear that nothing is wrong. The physician must use great caution to establish in the patient a delicate balance between a healthy respect for the possibilities behind a positive x-ray and at the same time help him face his anxiety. Here the physician goes from the objective aspects of medicine to the art of medicine.

The first clinic visit of a patient referred from a mass chest x-ray survey is loaded with expresent him with a bill for $10,000. That is the average cost in lost wages and medical expenses between diagnosis and end of treatment or death. But the physician is going to do even more than that. He will suggest segregating the patient from his family. This, of course, has profound sociological and biological implications. The latter are often responsible for the patient's failure to accept "the cure" or for not taking it well. This first clinic visit may determine whether the patient will accept the physician's recommendations at all, or whether he will continue to spread disease to the community and, if early treatment has value, throw away his best chances for future health. A careful history, and time to get acquainted with the patient and his problems, will make follow-up with community funds less

costly. A physician who makes disposition of a patient with an intrathoracic lesion needs all the information obtainable through the most meticulous history and physical.

By using four diagnostic aids in making a diagnosis of tuberculosis, or in ruling it out, the physician cannot go far wrong: first, x-ray examination and competent interpretation; second, competent and persistent bacteriological study; third, the tuberculin test; and fourth, a careful and detailed history and physical. A diagnosis of tuberculosis based on these criteria, or ruled out through them, is based on scientific fact. It protects the community and the patient. It will not needlessly disrupt the sociological, economic and biological needs of the patient and his family.

NEEDLESS DIPHTHERIA DEATHS

No matter how wonderful the discoveries of medical science, they are of no practical value unless applied. Neglect to make full use of preventive measures against diphtheria is proved by the fact that in 1946, there were 121 more deaths from this disease in the United States than in the record year of 1941. The *Journal of the American Medical Association* (Vol. 134, p. 1540) has gathered statistics from nearly a hundred cities of the deaths from diphtheria in 1946. Thirty-one municipalities had a perfect record. In ten more, the mortality was exclusively among nonresidents. Children who live in rural districts where immunization is not thorough are often taken to city hospitals if they become sick. Twenty-seven cities had no diphtheria or typhoid mortality in the year, seven others none of residents. Fourteen New England cities had four times as many diphtheria deaths as in the previous year. Boston had twenty-two, as against one each year in 1942 and 1943. It is clear that infants and preschool children should receive their protective treatments and protective boosters on entering school, and later in life when conditions indicate this is desirable.—*Good Health,* November, 1947.

EVALUATION OF ANTICOAGULANT THERAPY IN DEEP VENOUS THROMBOSIS OF THE LOWER EXTREMITIES

CLARENCE DENNIS, M.D.
Professor of Surgery, University of Minnesota
Minneapolis, Minnesota

THE high incidence of spontaneous thrombosis in the cerebral and coronary vessels needs little emphasis. The frequency of spontaneous thrombosis in the deep leg veins, however, has not been generally appreciated until recently. Hunter found such thromboses in 44 per cent of routine autopsies, usually primary in the calf and extending to the femoral only secondarily. The frequency was higher in medical than in surgical autopsies.

Diagnosis

Little time can be spared for discussion of diagnosis. Hot thrombophlebitis, with fever, leukocytosis, local heat, swelling, tenderness, and positive Homan's sign, lies at one extreme; bland thrombus formation or phlebothrombosis, with few signs—perhaps a pulse rise, slight soreness, or swelling—and with frequent early embolism, lies at the other. Any given case can lie anywhere in the range between.

Incidence

Barker and E. V. Allen, at the Mayo Clinic, estimate venous thrombosis to occur in 1 per cent of surgical patients, and fatal embolism to occur in one in five of these if specific therapy is omitted. In some groups, those with sepsis, those having pelvic operations, and particularly those with ulcerative colitis, the incidence is far higher.

Methods of Therapy

Various methods of therapy have been exploited:

1. Expectant therapy has been abandoned because of high immediate risk, five to six weeks of immobilization, and high incidence of permanent pain and edema.

2. Lumbar novocaine block of Le Riche and Ochsner is occasionally spectacularly successful but not regularly so. The University Hospital staff has almost abandoned it, primarily because of two fatal emboli immediately following injection.

3. Paine and Levitt found some benefit to follow intermittent venous occlusion.

4. Pendergass and Hodes found some decrease in edema to follow x-ray therapy.

5. Day found use of snug bandages and early walking effective. No experience with this therapy has been had at the University.

6. Fine, A. W. Allen, and others have advocated superficial femoral vein ligation in the prevention of emboli, and present very convincing figures. Veal and Hussey, and others, even tie the vena cava for many cases. The common femoral should not be ligated.[6]

7. Anticoagulant therapy employs heparin, first introduced as a therapeutic agent by Murray in 1938, and championed by many,[2,3,4,9,11] and dicumarol, isolated at the University of Wisconsin, and employed vigorously in clinical cases by Barker, E. V. Allen, and their associates at the Mayo Clinic.

Experience with Phlebitis

In association with Drs. H. P. Berge, W. P. Eder, and Kenneth Lister at the Minneapolis General Hospital, and with Drs. Davitt Felder, Ivan Baronofsky and George Moore at the University Hospitals, I have had an opportunity to evaluate several of these methods of therapy in the past few years. It soon became apparent that the choice to be made was primarily between the use of ligation and the use of anticoagulants.

Because there seem to be no reports in the literature on unbiased evaluation of these two modes of therapy, an effort was made to do so. A general plan was laid out, cases in 1945 being treated primarily by blocks and ligations at the University and primarily by dicumarol at the General; the modes of therapy were to be switched at the beginning of 1946 at each hospital. Unfortunately, I did not have control of all the cases, and numerous aberrations from the plan occurred, but the information obtained represents an honest effort to make the most of each type of therapy.

From the Department of Surgery, University of Minnesota Hospitals, and the Department of Surgery, Minneapolis General Hospital. Supported by a research grant from the Graduate School of the University of Minnesota.

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1947.

TABLE I. EXPERIENCE WITH THROMBOPHLEBITIS

	Minneapolis General	University	Total
Anticoagulants alone	27	65	92[1, 2]
Deaths	0	1[3]	1
Total femoral ligations	6	10	16[4]
Ligations alone	2	7	9
Deaths	1	1	2[5]
Ligation-dicumarol	4	3	7
Deaths	0	0	0

[1] Only three of seventy-six pateints followed had late pain or edema.
[2] Four patients had hematuria, which was disregarded; two patients had serious hemorrhage which stopped treatment, both are well.
[3] Inadequate heparin because of general sepsis and hemorrhagic diathesis; died of embolus.
[4] Four of twelve patients followed had late pain and/or edema.
[5] Emboli after ligation. One other patient developed hot thrombophlebitis three days after bilateral ligation for other side.

Mechanism

The mechanism of intravascular clotting is essentially as indicated in Figure 1. Thromboplastin is not normally free in plasma, but is released following agglutination of platelets. The result is a combination of calcium ion and prothrombin, both normally free in plasma, to form thrombin, which in turn combines with fibrinogen to form fibrin. Heparin interferes with at least two of these processes, possibly all. Dicumarol, on the other hand, lowers the prothrombin blood level by blocking production in the liver.

Employment of these drugs in phlebothrombosis is effective because it prevents propaga-

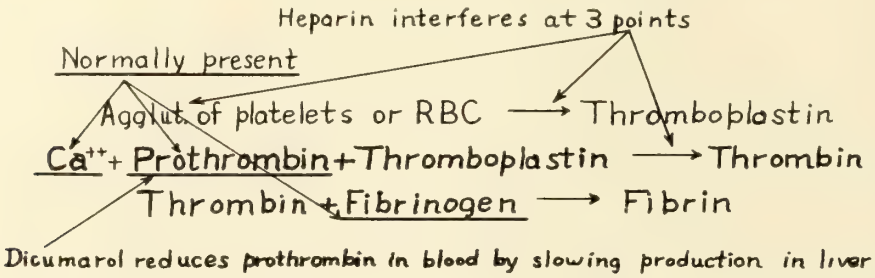

Fig. 1. Probable mechanism of intravascular clotting.

Blocks were disappointing and are omitted from this presentation. In the past year the anticoagulant therapy at the University Hospitals has been taken over by Dr. Davitt Felder, who has performed a superlative study on which he will report fully at a later date.

Table I indicates the combined experience. Of ninety-two patients given anticoagulant therapy alone, one death occurred. In this instance generalized sepsis and a marked hemorrhagic diathesis combined to make ligation impossible and anticoagulant therapy inadequately applicable; she died of embolus. Of these ninety-two patients, seventy-six have been followed; only three have late pain or significant edema. Two of these ninety-two cases suffered severe hemorrhage requiring cessation of therapy. Both are well today. Review of the occurrence of two fatal emboli after ligation, and the occurrence of hot thrombophlebitis in one patient three days after ligation of the superficial femoral vein, together with the high incidence of late symptoms, led all of us to be all the more impressed with the good record achieved with anticoagulants.

tion of the clot and blocking of venous and lymphatic collaterals. It is apparently only freshly formed clot which embolizes, and adequate anticoagulant therapy for three or four days allows the already formed thrombus to become firmly anchored without fresh clot formation; therefore full activity can then be allowed with little risk.

Plan of Use

In uncomplicated cases of venous thrombosis the combined experience has led to the use of dicumarol alone. As indicated in Figure 2, the usual plan is to give 300 mg. orally the first day and 200 mg. the second. Therapy thereafter is guided by prothrombin time determination daily, the value of which is the indication for each day's dose. The therapeutic range of prothrombin time is two and a half to three and a half times the value of the control from a normal person, which must be run with every batch of determinations because of the unavoidable variations in the thromboplastin which is added. Usually the therapeutic range is reached in about three days and the dosage required is about 100 mg. daily. Because of the lag in effect, the direction of the

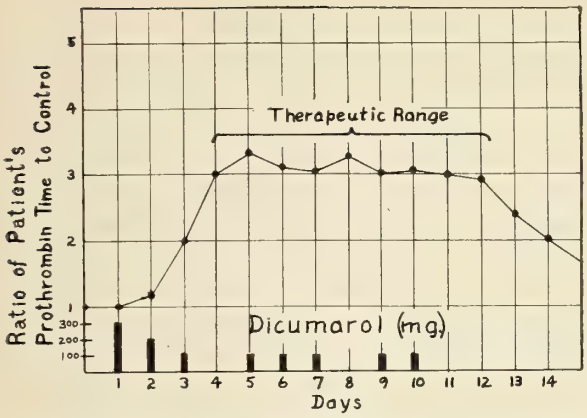

Fig. 2. Example of response of prothrombin time to dicumarol. Wide variations occur and daily prothrombin time determinations are essential.

curve as well as the absolute value must be used as a guide in dosage. Return of readings to normal requires five to fifteen days after cessation of therapy.

Hemorrhage is a serious complication, and may be concealed. Blood transfusion supplies enough prothrombin to bring the prothrombin time down to almost normal for eight to ten hours, but 60 mg. of synthetic vitamin K must be given at the time of transfusion to keep the level down. It is well to repeat this latter in another twelve hours. Minimal microscopic hematuria does not necessitate cessation of therapy.

For best results, patients are kept in bed until symptoms have disappeared, and therapeutic levels are maintained four to five days after ambulation begins.

In such acute emergencies as pulmonary emboli and rapidly spreading femoral thrombosis, the experience mentioned has led to the conclusion that heparin should be given intravenously, because of the quick response, until therapeutic levels of prothrombin time elevation have been reached with dicumarol. Continuous intravenous heparin drip infusion has been found too difficult to control and therefore dangerous. Preferable is intravenous injection of 30 to 50 mg. every three hours, the dose being adjusted to raise the capillary clotting time to 20 to 25 minutes at one hour after each injection. One or two clotting time determinations per day suffice. Clotting times are found to return approximately to normal before each injection.

Discussion

In general, the employment of dicumarol must be restricted to areas served by good laboratories where well-trained technicians are on hand for daily determinations. Prothrombin time determination is treacherous and not to be relied upon in the hands of a novice, and variations in response to dicumarol, and strength of different batches of the drug, make laboratory control absolutely imperative.

In areas not served by such a laboratory, heparin therapy on the plan indicated may be employed throughout the necessary period of therapy, usually running seven to fourteen days.

Prophylactic Use of Anticoagulants

My personal experience with the prophylactic use of dicumarol in patients undergoing ileostomy for chronic ulcerative colitis confirms the findings of Allen and his associates. In this disease 25 to 30 per cent develop venous thrombosis postoperatively in the absence of specific therapy. In the last twenty cases, only three patients did not have 100 to 300 mg. of dicumarol the night before operation; these three died of pulmonary embolism; all others recovered without evidence of venous thrombosis.

Conclusion

Combined experience at the Minneapolis General Hospital and at the University of Minnesota Hospitals indicates that anticoagulant therapy is more effective than other measures in the management of deep venous thrombosis in the legs.

The general plan of therapy is presented.

EARLY POSTOPERATIVE AMBULATION

CHARLES H. MEAD, M.D.
Duluth, Minnesota

EARLY postoperative ambulation is designed to maintain normal physiologic functions of the body after surgical treatment. The procedure denotes activity starting in the first six to twenty-four hours after operation, encouraging the patient to be up and about with continuation of normal physiological processes.

Prolonged postoperative bed rest exaggerates undesirable physiological changes, thereby increasing the possibility of critical complications during convalescence. The changes are caused by mechanical and nervous factors affecting the respiratory, circulatory, gastrointestinal and genitourinary systems. Prolonged bed rest produces pulmonary complications in 2 to 4 per cent of all surgical patients. Fifty per cent of such complications occur within the first twenty-four hours and 75 per cent within the first forty-eight hours after operation. Circulatory complications such as thrombophlebitis and pulmonary embolism occur in from 1 to 4 per cent of all surgical procedures. Approximately 25 per cent of surgical patients confined to bed have urinary retention and constipation.

Present-day surgical gentleness and skill combined with excellent anesthetic facilities permit handling and revision of various anatomical systems without effect on the rest of the body. Continuance of normal function of the remaining organism is maintained. Activity of the entire organism is conducive to adequate pulmonary ventilation. Atelectasis is further prevented by persistent cough activity and the coincident increased venous return produced by negative pressure within the thorax. Early activity maintains cardiac output with attendant good arterial supply and associated venous return insuring oxygenation of all parts. Thus, there is a complete avoidance of general and special tissue anoxemia due to venous and arterial stasis.

The procedure maintains function of the gastrointestinal system, unless continuity has been disrupted. Ingestion of fluids and regular diet produces a solid food bolus which continues normal forward propulsive intestinal peristalsis, thus eliminating collections of gas, abdominal distention and the necessity for catharsis or enema. Full activity of the genitourinary system is provided (inactivity of which seems to be related to dysfunction of the central nervous system in many instances), thus reducing or eliminating the need for catheterization and the frequent complication of urinary cystitis.

Activity of the central nervous system with good co-ordination thereof and improved general physiological function of the body is assured. Delay of institution of activity because of spinal anesthesia has long ago proved unnecessary, in that such activity need be delayed only long enough to permit resumption of function of the lower extremities.

The only hazard of early postoperative ambulation is disruption of an operative wound. If the wound has been properly secured by gentle, complete, smooth apposition without traction, disruption of the wound in an ambulatory patient is no more frequent than in a bed patient. Poor wound apposition produces frequent disruption, whether the patient be in bed or active, and without regard to closure material. Disruption of a wound is usually predictable because of known malnutrition or inadequate closure. Prevention of disruption of abdominal wounds may be aided by primary reinforcement of all questionable wounds at the time of repair. Such wounds should not be subjected to early postoperative ambulation.

Limitations of the procedure must be recognized, and use of the method must be tempered with adequate judgment. It is evident that the procedure cannot be patternized but must be fitted to each individual case. Nevertheless it is suited for the clean, uncomplicated case. The individual seriously injured by chemical, bacterial, or traumatic agents, still requires the basic therapy of complete rest with controlled physiology, chemotherapy, et cetera, and is not amenable to early ambulation. Thus, the latter must take the additional risk incident to prolonged bed rest.

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1947.

Method of Ambulation

Postoperative orders concerning early ambulation note the following procedures:

1. "MS gr. 1/6 or 1/4 prn q 4 h for pain." It is noted in all cases of early postoperative ambulation that the number of doses of such medication is greatly reduced and within two to three days proves entirely unnecessary.

2. "Ventilate (CO_2) and cough q 15 minutes x 4—q 1/2 h x 4—q 1 h x 4—then q 2 h." This order is designed to encourage ventilation and hyperexpansion of the pulmonary system, and reduce collections of mucus or mucous plugs. There is a coincident increase of intrapulmonary negative pressure, with aspiration of venous blood through the vena cava and increased venous flow and reduced venous stasis. The latter effect minimizes the production of thrombosis in the large vessels of the lower extremities and the pelvic region, and decreases the number of postoperative embolic phenomena from such thromboses. The order in relation to ventilation includes a secondary order wherein the patient is directed to cough at regular intervals, supporting the abdominal wound with the hand. It is felt that active coughing again minimizes collection of mucus and formation of mucous plugs, decreasing pulmonary atelectasis and collapse.

3. "Move lower extremities and turn from side to back to side q 15 minutes x 4—q 1/2 hr x 4—q 1 h x 4—then q 2 h." This order is intended to facilitate muscular activity of the lower extremities as well as drainage of the venous system by gravity, muscular activity acting as a pumping mechanism to insure venous flow and activity. The turning process is designed to avoid posterior pulmonary congestion or hypostasis, and also permits increased pulmonary ventilation.

4. "Patient to stand (or sit) at bedside to void." This order is designed to encourage the patient to resume weight bearing as soon as possible, and facilitates urination, particularly in male patients, many of whom find it difficult to void while in the supine position.

5. "Encourage full back rest at once." The patient is encouraged to assume a normal sitting posture as soon as his general anesthesia permits. No delay in assuming such position is afforded the patient because of having a spinal anesthesia, as experience has noted that the number of individuals developing a postoperative spinal anesthesia headache is no greater in those who assume activity at once than in those who are placed under a regime of delayed activity and flat in bed position. The patient is ordered up in a chair at the end of twenty-four hours and permitted to move about to the bathroom and as he may desire.

6. "All fluids and a regular diet at once." The function and mechanism of the gastrointestinal tract is carried on as before operation to afford no change in the normal physiology thereof. The exception, of course, is where there has been any profound disruption of the intestinal tract, which necessitates rest thereof during its own healing process.

These orders and procedures are applicable to most patients. Modification of an early ambulation program is necessary for the individual who is psychosomatically unable to adjust to such procedure. Patients should be informed and instructed concerning the conduct of their postoperative treatment when early ambulation is intended.

UNIVERSITY OF TEXAS SPONSORS FIRST MEDICAL DEPARTMENT AFFILIATED UNIT

The University of Texas is the first institution to become a member of the Army Medical Department's Postwar Affiliation Program, Brig. General George E. Armstrong, Deputy Surgeon General, announced recently.

Additional units, both general and evacuation hospitals, from other leading medical schools and hospitals throughout the country will be activated this year.

The professional members of these new hospital units will be drawn from the faculties and staffs of the medical schools and hospitals which sponsor them. The personnel will be trained in Army methods and procedures so that in the event of mobilization these units will be prepared to take the field with the minimum of delay.

In World War II there were seventy-three units, comprising general, evacuation, and portable surgical hospitals, which were brought into the service. These affiliated units make an important contribution to the high standards of medical care given by the Medical Department during the war.

The Medical Branch of the University of Texas sponsored a general hospital—the 127th—in World War II from October, 1943 to September, 1945. The 127th General Hospital performed outstanding service in the European Theatre of Operations.

The school has agreed to sponsor a 1,000 bed general hospital in this postwar program. Dr. Chauncey D. Leake, Vice President of the Medical Branch of the University of Texas, signed the agreement with the Department of The Army. This medical school is located at Galveston, Texas.

HYPERTENSION—MEDICAL TREATMENT

WILLIAM D. COVENTRY, M.D.
Duluth, Minnesota

THE importance of hypertension as a medical problem becomes apparent when it is realized that about 15,000,000 people in the United States have some degree of elevation of the blood pressure.[20] When one reflects upon our lack of understanding of the origin of this disorder and our lack of progress in its treatment, the great magnitude of the problem is again apparent.

In such a widespread disorder as this one, it is natural for the layman to hold certain views concerning it. These have in large part been based upon mortality statistics derived from insurance companies, all of which tend to emphasize the high death rate associated with hypertension. That this is true cannot be denied. However, there is a phase of the prognosis of hypertension which has received little attention; perhaps it does not lend itself easily to statistical analysis. It is the fact known to all physicians that many hypertensive individuals have a favorable outlook for a normal life expectancy, with relatively little impairment in health. This is especially true of women. Our viewpoint on prognosis should acknowledge this brighter side and emphasize it. Perhaps in the future, statistics on this optimistic phase of the prognosis will be available.

Any plan of treatment which is used should be carried out with due regard to certain well-known collateral clinical observations. For instance, it is fundamental to know that individuals with hypertension show marked variations in blood pressure throughout the day. The first reading taken in the doctor's office is almost invariably higher than the second one taken hours later. Consequently, if the effects of treatment are to be assessed, basal before and after levels must be taken. Palmer[12] has reported that transient normal levels are seen in 23 per cent of cases of early benign hypertension, 11 per cent in moderate hypertension, 8 per cent in advanced cases and 8 per cent in malignant cases.

At this point it might be well to say a few words about transient nervous hypertension. This syndrome occurs between the ages of eighteen and fifty, and when present may confound the examiner who wishes to make a decision as to the presence or absence of hypertensive disease. Levy et al[11] studied the military records of many thousands of army officers with this syndrome, and brought forth the conclusion that individuals with transient hypertension are more likely to develop sustained hypertension than those with normal pressures, and, furthermore, if transient tachycardia and overweight were also present, the predisposition was still greater. When one encounters an individual with transient hypertension, he probably should be regarded as a future permanent hypertensive. However, a great deal of harm will be done if the treatment from this standpoint is too vigorous or too dogmatic, for there are a certain number of these individuals—the figure has not yet been determined—who will never develop permanent hypertension, and these may be harmed by ill-considered advice. Rogers and Palmer, in a small group of patients with transient hypertension followed for more than three years, found that half of them still had normal blood pressures. The ultimate prognosis of individuals with transient hypertension in terms of percentage must await further long-range studies. In regard to fluctuating blood pressures, it might also be mentioned that the hyptension seen at the menopause has been shown to have no relation to the hormonal disturbance present.[18]

At the present time, the theory of renal ischemia as a cause of human hypertension lacks convincing proof. Renal disease is a definite causative factor in rare instances, but is not the universal cause of the disorder, and renal ischemia is not obligatory to the hypertensive state. The cause and perpetuating mechanism of essential hypertension is unknown.[15] Obviously no treatment we have at present can act on the cause of the disorder. Our efforts are directed at relieving symptoms as they appear and at reducing the arterial tension which is the most easily measured manifestation of the disease.

Medical treatment will now be considered in terms of psychotherapy, diet and drug therapy.

From the Department of Internal Medicine of The Duluth Clinic, Duluth, Minnesota.
Read at the annual meeting of the Minnesota State Medical Association, June 30, 1947, at Duluth, Minnsota.

Psychotherapy

Every physician has observed the fact that emotional and nervous reactions may elevate the blood pressure. Psychotherapy simply consists of helping the individual neutralize or diminish these reactions, and thereby produce a trend toward lower blood pressure levels. This type of therapy is particularly suitable because most hypertensive individuals are burdened with more than their rightful share of nervous reactions.

A study of the personality from the psychologic standpoint has been made by Binger.[3] His results, based on a study of twenty patients, show that "the hypertensive individual has a neurotic personality disorder, manifested in interpersonal relationship, in sexual adjustments and occupational achievements. He is characteristically tense and given to states of anxiety and depression. Much of this emotional tension can be ascribed to inhibited, but not deeply repressed, aggressive impulses." This neurosis, no doubt, explains in part many of the symptoms of the disorder, such as headaches, palpitation, weakness, shortness of breath, dizziness, et cetera, and provides a fertile field for psychologic reorientation. Simple psychotherapy may be very beneficial in relieving symptoms, if skillfully applied; in more profound states the aid of the psychiatrist must be sought. Weiss, a psychiatrist who has treated many of these patients, states that "almost every patient can be benefited by psychotherapy."

Tact is of the essence in handling these patients, and the power of the spoken word must be fully appreciated by the physician. When, after the careful evaluation of repeated readings, it is concluded that hypertension exists, a frank discussion of the subject with the patient should be undertaken immediately. This provides an immediate basis of understanding which will encourage the patient to seek advice from the physician in the future rather than from well-wishing friends. At this interview the prognosis should be discussed, and the patient should be reassured that the living out of a normal life span is possible. The normal variability of blood pressure readings should be explained.

In discussing level of blood pressure, it is wise to avoid absolute figures, but rather to speak of a blood pressure tendency toward elevation or depression. It is also good practice to avoid mentioning medicines which will bring "the blood pressure down"; medicines should be prescribed for the disease as a whole. In order to combat the common fear that high blood pressure will cause arteries to "blow out," it can be stated that healthy arteries will stand a pressure not only of 300 mm. but as high as 2,000 mm. of mercury.[4] Return visits should be encouraged, and actual blood pressure determinations eliminated from as many of these visits as possible.

In addition to the proper psychologic orientation of the patient, the benefits of a sensible regimen of rest and relaxation should be emphasized. Enforced bed rest is seldom necessary. Prolonged bed rest may lead to invalidism even though it results in lowering of the blood pressure, and should be avoided. In regard to exercise, one need only remember that moderate exercise is another way of producing relaxation and easing nervous tension. It also increases the caloric expenditure and therefore may benefit the obese patient.

Diet Therapy

Of various diets proposed for the treatment of hypertension, the reduction diet has the greatest usefulness, for many of these patients are obese. This diet has no permanent or transient effect upon the blood pressure, but by decreasing the body weight it does decrease the strain on the heart, and in this way prevents cardiac failure. The low-salt diet has had time-honored recognition, but its actual vasodepressive effect is doubtful. Recently, Grollman[6] has produced a decrease in blood pressure with a diet of rigid sodium restriction. However, the careful measurement and special processing of food required precludes its general use. The rice diet of Kempner[9,10] has aroused much interest. It is composed mainly of rice, fruit and sugar, with a low sodium and low protein content. This diet is monotonous and unpalatable and has not had widespread acceptance.

Smoking

What advice should be given the patient in regard to smoking? It is well known that smoking causes a decrease in peripheral blood flow and an increase in the blood pressure and heart rate in normal young persons. It has further been found that in young hypertensive individuals and in older hypertensives with vascular disease, there is a trend towards decreased peripheral blood flow with increased heart rate and blood pressure after smoking.[16,17] It would appear, therefore, that smoking cigarettes has a deleterious influence on

the vascular disturbance in the hypertensive individual, and probably should be eliminated.

Drug Therapy

A survey of the use of drugs in the treatment of hypertension merely serves to re-emphasize the fact that a substance, easily administered, with a prolonged hypotensive action and without toxic effect, is yet to be found. Nitrites, iodides, veratrum,[8] kidney extract, hormones and vitamins are of no proved value.[1] The action of Etamon (tetraethyl ammonium chloride), a powerful vasodepressor, is too fleeting and would not seem to qualify as a suitable drug. The results from irradiation of the pituitary gland need further confirmation[13] The sedatives are very useful for the relief of symptoms but their prolonged use should be guarded against. They have no sustained effect on the blood pressure.

Potassium thiocyanate has been used widely in this country since Barker in 1936 introduced a method of blood assay which greatly facilitated the control of dosage. However, even after ten years of extensive trial the value of this drug and the indications for its use are not agreed on.[7] It appears to be effective in lowering the blood pressure and relieving syptoms in hypertension. A sustained fall in blood pressure can be expected in about 43 per cent of the patients to whom it is administered and complete symptomatic relief in 50 per cent.[2,5,19] It is especially beneficial in relieving severe headaches and dizziness. A disadvantage of thiocyanate therapy is the close observation of the patient which is necessary in order that the dosage and blood concentration be kept satisfactory. This requires repeated venous blood determinations throughout the course of treatment. Mild toxic effects occur in 20 per cent of the patients but usually do not require discontinuance of the drug. The dosage varies considerably in different individuals. The drug is contraindicated in renal insufficiency, extensive cardiac or cerebrovascular arteriosclerosis and in malignant hypertension. It does not relieve the anginal syndrome or exertional dyspnea seen in hypertension. It also appears to have no effect in retarding the atherosclerotic process or in diminishing the organic failure resulting therefrom.

Two methods of administration are used. White[21] recommends beginning with 3 grains daily, checking the blood level at the end of two weeks, then increasing the dose by 1 to 3 grains daily, until a satisfactory fall in blood pressure occurs. At this point a maintenance dose is established. The patient must, of course, be continuously observed for toxic effects. He has found that good results occur with blood levels as low as 4 to 7 mg. per cent and with doses as varied as 3 to even 15 grains daily. If a two months' trial is not effective, the therapy should be discontinued. Hines[7] advises an initial daily dose of 12 grains and subsequent dosage adjusted to maintain a blood level of 8 to 12 mg. per cent. His maintenance dose usually varies between 6 and 9 grains. A concentration test should be made every week until a maintenance dose is determined. Even on a maintenance dose, the level should be determined every two or three months. This drug is most suitable for use in patients below the age of fifty with little or no evidence of arteriosclerosis, and with symptoms, especially severe headaches.

Finally, a word about the patient in the geriatric age. The patient over sixty with hypertension but little focal arteriosclerosis and minimal symptoms is in a very favorable position. He needs no treatment whatever for his hypertension. Many fall into this group. Most individuals, however, are not so fortunate and have some degree of arteriosclerotic organ involvement by this time. We can do relatively little to head off impending cerebrovascular or renal failure, but by periodic attention to cardiac function, early heart failure can be recognized and effectively treated with digitalis and diuretics.

In summary, the medical management of hypertension involves, in order of importance, the use of psychotherapy, drugs and diet. It is essentially a conservative treatment in view of the unknown pathogenesis of the disorder. Our aim should be to treat the patient and the disease as a whole, not just the blood pressure level.

HYPERTENSION—SURGICAL TREATMENT

HAROLD F. BUCHSTEIN, M.D.
Minneapolis, Minnesota

A NUMBER of considerations have stimulated renewed interest in the treatment of essential hypertension by means of operations on the sympathetic nervous system. Chief among these has been a growing awareness of the prominent role played by hypertension as a cause of invalidism and death. Hypertension is being recognized as a killer even more malignant than cancer. The discovery of numbers of men with hypertension in the armed services has focused attention on the problem of the treatment of hypertension in young adults. Medical measures of treatment have proved inadequate and impractical in many cases. The hoped-for anti-pressor substance is not vet available, and regimens emphasizing rest and inactivity are not accepted by many patients. Finally, the development of more effective surgical techniques has given new hope to those hypertensives falling within their scope.

Surgical Techniques

The surgical treatment of essential hypertension is based upon the assumption that vasoconstriction of neurogenic origin is an important factor in the production and maintenance of the elevated blood pressure. The object of surgery is to denervate a large portion of the vascular bed, particularly in the splanchnic area, together with the kidneys and adrenal glands.

A member of this society, Dr. Adson, enjoys the distinction of being the first surgeon to attack this problem. In 1925 he and Rowntree reported the case of a patient upon whom bilateral removal of the lumbar sympathetic trunks was performed in an unsuccessful effort to relieve malignant hypertension. Believing that a more complete denervation was required to produce a satisfactory result, Adson subsequently carried out a more extensive procedure, the sectioning of the anterior (motor) spinal nerve roots from the sixth thoracic to the second lumbar levels. This operation required an extensive laminectomy and carried a definite risk of spinal cord trauma. For this reason it was eventually abandoned, but not before it had been conclusively demonstrated that the blood pressure could be significantly and permanently lowered in cases of severe hypertension, and that such lowering of the blood pressure was not, as some had postulated, harmful to the patient.

Following the suggestions of Italian surgeons, the next attack was upon the splanchnic nerves and the adjacent portions of the sympathetic trunk. Craig and Adson removed these structures just below the diaphragm through a retroperitoneal exposure. This operation was relatively simple of performance and carried an amazingly low mortality. However, its results were disappointing except in mild cases, and it was gradually abandoned.

Peet (1933) at the University of Michigan removed segments of the splanchnic nerves and sympathetic trunks just above the diaphragm, gaining exposure by removal of portions of the eleventh ribs. This operation, which has now been performed on over 1,500 patients in Peet's clinic alone, carried a somewhat greater risk than the Craig-Adson operation, but it was also more effective.

In an effort to achieve a still larger percentage of favorable results, Smithwick (1938) devised a more extensive operation which was essentially a combination of the Craig-Adson and the Peet techniques. Through an incision extending from above the tenth rib into the flank, the splanchnic nerves are removed from the ninth thoracic level to their termination in the celiac ganglion, and the sympathetic trunk is removed from the ninth thoracic to the second lumbar levels. The procedure is carried out bilaterally, at an interval of about eight to ten days. This thoraco-lumbar sympathectomy is at present the standard operative procedure employed in the treatment of hypertension. It is more effective than the less extensive operations, yet it has a mortality in expert hands of only about 1 per cent (case mortality 2 per cent). It does have a not insignificant morbidity, however, as approximately a month's hospitalization is required for preoperative tests and the two operations, and postoperative discomfort from nerve irritation is considerable in many patients.

Read in the symposium on Hypertension at the annual meeting of the Minnesota State Medical Association, June 30, 1947 at Duluth, Minnesota.

Even more extensive sympathectomies have been carried out by Grimson (1941) and Poppen (1942). It is not yet apparent if they yield results which are sufficiently superior to justify the additional risk and effort which they entail.

Results of Operation

It has been a common observation that the result of operation in an individual case is difficult to predict and subject to wide variation. Only by the study of large groups of cases followed for several years postoperatively, and a comparison of their course with that of similar groups of patients treated medically, can a true estimate of the worth of these operations be obtained. Fortunately, a number of such reports by both medical and surgical observers are available, some of them extending over as long a follow-up period as twelve years. The reader is referred to the original papers for statistical details. Comparisons between the reports of different authors is difficult because of the varying standards adopted for the selection of cases for operation and for the evaluation of results. It is clear from a study of these reports, however, that while surgery is seldom to be regarded as a cure for hypertension, it does yield results for certain groups of patients which are decidedly superior to those produced by medical treatment.

The beneficial results of operation in successful cases may be considered under three headings:

Subjective Symptoms.—It has been a universal observation that subjective symptoms such as headache, dizziness, palpitation and a feeling of "inner tension" are dramatically relieved in a high percentage of cases, including many in whom there is little or no lowering of the blood pressure. This has been attributed to denervation of the adrenal glands. These results, while admittedly subjective, are frequently very gratifying to the patient, particularly when they permit him to return to a gainful occupation. Relief from severe and disabling headaches is particularly welcome.

Objective Findings.—Chief interest attaches to the effect of operation upon the blood pressure level, and this tends to become the sole criterion by which the result of operation is judged. For purposes of comparison both preoperative and postoperative pressures should be determined under similar circumstances, preferably after a period of bed rest, and pressures should be compared in both the recumbent, sitting and standing postures. It is manifestly unfair to compare a preoperative reading obtained after a period of rest with a postoperative reading obtained in the physician's office.

During the first weeks following operation many patients display a marked orthostatic hypotension. Assumption of the erect posture is followed by a precipitous fall of blood pressure together with palpitation, giddiness, and even syncope. It may be necessary for the patient to wear a snug abdominal binder and even to wrap the legs with elastic bandages in order to stand up. These effects tend to wear off in the course of a month or two, but some fall of blood pressure on assumption of erect posture may persist indefinitely. A number of patients will demonstrate a fall of blood pressure on exercise postoperatively rather than the normally encountered rise.

Three recent follow-up reports demonstrate the beneficial effect of operation on blood pressure levels. Peet, reporting on 437 cases followed for from five to twelve years after operation, found that 46.7 per cent showed a significant reduction in blood pressure at (least 40 mm. systolic and 15 mm. diastolic). Among patients still living, 81.3 per cent showed a significant reduction. It may be mentioned that Peet's patients included a relatively large number with advanced and malignant hypertension. The results were naturally superior in those with milder forms of the disease.

Poppen, reporting on 100 consecutive patients subjected to an extensive sympathectomy and followed for one and a half to four years, found that 47 per cent had good results, i.e., a reduction of blood pressure to nondangerous levels, and relief of symptoms, the patient being in good physical condition. An additional 24 per cent of patients had a fair result, i.e., they were relieved of symptoms, were in good health, but had experienced a lesser fall in blood pressure although all pressures were in a range regarded as relatively nondangerous. A satisfactory result was obtained in 71 per cent of patients.

Palmer, reporting on a group of Smithwick's patients, found that whereas early in their postoperative course two-thirds of the patients had blood pressures which were normal or nearly normal, at the end of three years only 25 per cent maintained this level. However, a similar

group of patients treated medically with thiocyanates yielded only one-half as many favorable results.

These three reports are not comparable one with the other because the types of cases treated and the criteria for judging results vary among them, but they all demonstrate the effectiveness of surgical treatment and its superiority over medical management.

Objective improvement is not limited to blood pressure levels alone. Improvement in funduscopic findings, with disappearance of hemorrhages, exudates and edema has been frequently observed following operation, whereas such an occurrence is rare indeed under medical treatment. Localized angiospastic changes frequently are observed to disappear; sclerotic changes, of course, are permanent.

A significant percentage of patients noted to have enlarged hearts and electrocardiographic changes preoperatively show a return of such findings to or towards normal. However, patients presenting actual hypertension heart disease with congestive heart failure are not often benefited.

Careful rechecks of kidney function have demonstrated that most patients presenting normal or nearly normal findings preoperatively will maintain their level of kidney function for long periods postoperatively, and some show improvement. But those patients in whom actual nitrogen retention in the blood was present preoperatively are seldom benefited by surgery.

Longevity.—Perhaps the best demonstration of the efficacy of surgery in the treatment of hypertension is provided by studies of mortality rates in comparable groups of patients under medical and surgical management. The statistics of Keith and Wagener provide the best available standard against which to test the results of surgical treatment. Peet has presented such a comparison. His statistics show that whereas only 60 per cent of those with mild (Group I) hypertension survived for five years under medical management, 100 per cent of such patients subjected to operation lived a similar time. Among patients presenting evidence of more advanced hypertensive disease with organic changes in the blood vessels, heart and kidneys (Group II), the advantage in favor of the group operated upon was much less striking. Greatest interest attaches, however, to patients with malignant hypertension (Group IV), that is, those who present evidence of retinal edema together with a rapidly progressive hypertension. Under medical management 79 per cent of such patients die within a year and 99 per cent within five years. Longevity following operation is strikingly increased; 19 per cent of 112 patients with malignant hypertension operated upon by Peet were alive at the end of five years.

Palmer has also emphasized the good results to be obtained in cases of malignant hypertension subjected to operation before the onset of renal and cardiac failure.

Selection of Patients for Operation

The judicious selection of hypertensive patients for surgical treatment involves both scientific and humanitarian considerations. Adherence to too strict standards will permit the compilation of an enviable set of statistics, but will exclude many borderline patients who, facing inevitable disaster, will be denied their chance for help. Adoption of too liberal a policy, on the other hand, will yield so many poor results that the reputation of the surgical method will suffer and patients will be sujected to needless inconvenience and expense.

A review of the literature shows a considerable diversity of preoperative criteria for the selection of patients. Attempts to set up tests, usually relating to the behavior of the blood pressure under various conditions of stimulation and sedation, have not been too successful in predicting favorable responses to operation. On the other hand, certain indications of a probable poor result have been discovered and these appear to be much more consistent. Thus the process of case selection is largely one of exclusion.

It is, of course, assumed that in the patient under consideration other causes of arterial hypertension, such as unilateral kidney disease and pheochromocytoma, have been excluded.

Most authors find that patients in the younger age groups, presumably having less vascular sclerosis, are more favorable subjects. The optimum age for operation is below forty years, and rarely is there occasion for operating on patients over fifty. Females are notoriously more tolerant of hypertension than males, and as a group they yield better results following operation.

A family history of hypertension, with a record of parents and close relatives dying as young adults of strokes, Bright's disease, or conges-

tive heart failure, should certainly dispose one toward advising operation at as early an age as possible in patients showing unmistakable evidence of progressive hypertension. If operation on a purely prophylactic basis is ever justified, it is in this group.

The preoperative study of the patient's blood pressure should be carried out over a period of time and under varying conditions of activity and rest. Smithwick has particularly emphasized the difficulties of estimating the true state of the patient's blood pressure from single examinations, particularly those performed in the doctor's office, since these usually represent maximum readings. It should be demonstrated that the patient has a persistent elevation of blood pressure and that it is progressively becoming higher in spite of medical management.

The lability of the blood pressure may be checked by recording hourly readings over a twenty-four to forty-eight-hour period of bed rest, and by similar hourly recordings after heavy sedation (sodium amytal gr. 3, hourly for three hours). A labile blood pressure is no guarantee of a good result following operation, but a relatively fixed blood pressure practically excludes it. Smithwick has found that when the pulse pressure, determined at rest, is less than one-half the diastolic pressure, the prognosis for improvement is good, while if the pulse pressure approaches or exceeds the diastolic, the chances for success are poor.

Careful study of the patient's fundi is most important for it provides an estimate of the degree of arteriolar sclerosis present. Observable also may be evidences of active vasospasm and retinal edema. The latter indicates that the case is one of malignant hypertension.

Study of the heart size and function, electrocardiography, and careful tests of kidney function are essential to exclude unsuitable cases. As previously indicated, patients with congestive heart failure and nitrogen retention in the blood seldom obtain worth-while results. Evidence of more than minimal coronary artery disease in the electrocardiogram should exclude the patient since coronary closure accounts for most of the few operative fatalities.

A history of cerebrovascular accident, if not in itself disabling, is no contraindication to operation, provided the patient is otherwise suitable.

Contraindications for Surgery

1. Mild, nonprogressive hypertension.
2. Age over fifty years.
3. Fixed blood pressure level with a high pulse pressure.
4. Nitrogen retention in the blood.
5. Coronary artery disease.
6. Congestive heart failure.

Indications for Surgery

1. Progressive, labile essential hypertension in a patient under forty years of age, without evidence of important organic changes in the blood vessels, heart, or kidneys, especially in the presence of disabling subjective symptoms and/or a family history of early hypertensive deaths.
2. Early malignant hypertension, before the onset of renal and cardiac failure.

Conclusion

Surgery in the form of thoracolumbar sympathectomy is the best available treatment for some patients with essential hypertension. Properly applied, it is a safe and effective method which will alleviate symptoms and prolong life. It is not a last resort or a measure of desperation and should be offered to the patient while he is still in a condition to obtain its full benefits.

ABDOMINAL EMERGENCIES IN GENERAL PRACTICE

J. F. NORMAN, M.D.
Crookston, Minnesota

IN this paper only a few of the acute abdominal emergencies will be discussed. The need of the physician to develop an awareness of the possibilities of the symptoms of continued abdominal pain is evident. The presence of abdominal pain associated with nausea and vomiting which has been present for six hours or longer must be considered as evidence of a serious lesion of the abdomen and one which in most instances requires surgical interference.[5] One cannot see such patient and promise to return later. The responsibility for the care and recovery of the patient is definitely in the hands of the physician who first sees him. The care of these patients will constitute about 10 per cent of all general major surgery in the average rural hospital.

A brief report of such patients seen in Bethesda and St. Vincent's hospitals in Crookston may be descriptive of those seen in similar hospitals throughout the state. Both hospitals are approved by the American College of Surgeons; both are fifty-bed hospitals, but each has been caring for up to eighty patients per day recently; both have excellent laboratories; and the same men are on the staffs of both hospitals. There is a trained and resident anesthetist in each hospital. The cases here reported were cared for by the members of the staffs of both hospitals.

During the two years 1945 and 1946, 8,151 patients were cared for, exclusive of newborn. There were 1,324 major operations, of which 135 were acute abdominal emergencies. Of these, 104 were acute appendicitis, of which sixteen were perforated. There were five cases of perforated peptic ulcer; seven cases of ruptured tubal pregnancy; two cases of intussusception; five cases of intestinal obstruction and twelve cases of other diagnosed conditions. There was no death among the appendicitis cases.

The physician who is called to see a patient with symptoms indicating an acute abdominal emergency is faced with a most tremendous responsibility, as the life of the patient is entirely in his hands. An attempt at early diagnosis must be made, and once the diagnosis has been made, early operation is mandatory. If a diagnosis is not immediately possible, the attending physician should not hesitate to ask for consultation and to take his patient to the nearest hospital where laboratory facilities are available. If it is evident that he is dealing with an acute abdominal condition, early operation should be done without spending valuable time in confirming or rejecting a tentative diagnosis. An exploratory laparotomy will carry little risk, while delay will result in a high mortality. These cases require quick thinking and sound judgment, as the mortality rate varies directly with the delay in operation.

In dealing with these emergencies, one's first concern should be the saving of the patient's life, doing a minimal amount of surgery and planning a secondary operation later if necessary. The physician should avail himself of every possible therapeutic agent. Most of these patients are first seen by a general practitioner who will have hospital facilities available at a short distance. Many of these patients will undergo operation at the hands of a general surgeon, especially in the rural areas.

The physician is usually called in these cases because of the patient's complaint of severe abdominal pain. At present, hospital facilities are within a short distance of the patient by automobile or ambulance, and he should be given the added advantage that early hospitalization gives him. An early attempt should be made to eliminate the question of medical conditions simulating surgical disease. Here again, pain may be the principal or only complaint, and this will bring to mind the acute abdominal symptoms arising from such conditions as pleurisy, pneumonia, coronary disease, spinal nerve pain, diabetic conditions and others. After it has been decided that the pain is really due to some acute abdominal condition, the attempt to make a differential diagnosis should be made. One will remember that most acute abdominal conditions will arise from (1) inflammation, (2) obstruction, (3) perforation, or (4) hemorrhage.

Improvement in mortality rates in the surgical care of these patients has been outstanding in the last ten or fifteen years. This is due not so much

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1947.

to improved surgical technique as to better preoperative and postoperative care; improvement in general anesthesia (gas with curare and sodium pentothal); better spinal anesthesias; the more frequent use of transfusions, whole blood or plasma, preoperative and postoperative; the use of sulfa drugs and penicillin; and early ambulation. Wangensteen suction with either a Levine or a Miller-Abbott tube has saved lives; amino acid therapy promises to save additional ones. Surgical technique as applied to acute abdominal emergencies has not changed much in the last ten years.

In the past the surgeon devoted much attention to perfecting surgical technique, assuming that if an operation was well done the patient should be assured of recovery. It is now well established that while careful technique is essential it is only one of the factors which will enter into the problem of making the patient's chances of recovery better. Other factors include the correction of deficiencies due to diet or disease or vomiting. This may be done by intravenous therapy in most instances, as the case is an emergency, and will consist of the administration of water, blood and plasma, glucose, and other substances including electrolytes and vitamins.[2]

Trauma will be diagnosed early because of history of accident or because of wounds of the abdomen. Such abdominal wounds may be penetrating or nonpenetrating; the latter cases cause some diagnostic difficulty. Treatment usually consists of suturing the small intestine with no drainage in early cases and doing an exteriorization of the large bowel. It is the continual leakage of fecal contents that makes such wounds dangerous, while small punctures will often heal spontaneously. Patients seen late are often better treated expectantly with the hope that perforations and other trauma may be finally well walled off. Lacerations of solid organs will be looked for.[6]

Appendicitis remains the greatest single cause of abdominal emergencies, and appendectomies will constitute 50 to 70 per cent of all operations for acute abdominal conditions. Appendicitis is typical of the inflammatory type of acute abdominal conditions. In the last thirty years this disease caused the deaths of 500,000 persons—a sizable army.[4] The New York Life Insurance Company reported that of one thousand deaths of policyholders in 1937 fifteen were due to appendicitis. Abell reported 20,000 deaths in 1940. Any disease which causes so many deaths is deserving of study. The development of the present era of surgery can nowhere be better demonstrated than in the treatment of acute appendicitis. It is believed that recent trends will mean a rapid lowering of mortality rate.

In the last twenty years four major contributions to surgery have been applied to the treatment of acute appendicitis. These are (1) intragastric suction, (2) intravenous fluids, (3) whole blood and plasma transfusions, and (4) chemotherapy and antibiotic therapy. Early ambulation might be added. This has reduced the mortality rate in the presence of perforation by 50 per cent. There has been a much less spectacular reduction of mortality in cases without perforation.[7]

The question of whether or not to drain has been discussed very much in the past. It appears that drainage of the peritoneal cavity for appendiceal peritonitis carries a very high mortality as compared to the case which is not drained. The same is true of appendiceal abscess where the better treatment is removal of the appendix where possible, closure of the peritoneum, and drainage to the peritoneum. Postoperative complications will be much less.

Perforated peptic ulcers are relatively common. Pain is the initial symptom and is so intense that it completely incapacitates the patient at once. The history of sudden onset, perhaps a past history of "indigestion," and the boardlike abdomen with evident great pain should cause the examiner to be on the alert for this condition. The patient who is seen two to four hours later may have confusing symptoms in that he may feel better and the rigidity may be less. It is at this stage of the disease that mistakes in diagnosis are common.

Graham's trinity of signs and symptoms indicative of intraperitoneal irritation apply to perforated peptic ulcer cases: (1) pain and tenderness; (2) one point of maximum tenderness; (3) it hurts the patient to roll over in bed. When the added symptom of rebound tenderness is present, the condition demands a laparotomy.[3,11] Surprisingly, cultures are frequently negative and peritoneal infection is not always present in fatal cases, but not many surgeons at present will follow Taylor[8] and others in treating these cases medically with suction, et cetera. Operation is indicated as early as possible. Here again, time

should be taken for careful preparation of the patient, and suction preoperatively and postoperatively may be life saving.

Black and Blackford[1] advise early but conservative operation for perforated peptic ulcer. Drainage is not necessary if operation is done in the first six to eight hours. After twenty-four hours or more they state that conservative nonsurgical treatment with continuous nasal suction may be the best possible. Vaughn[9] feels that if the patient is seen twenty-four or more hours after perforation, operative interference may lessen chances for recovery by breaking down adhesions which have closed the perforation, and that continuous nasal suction may be the best treatment. Wangensteen[10] in 1935 used suction in perforated ulcer cases when operation was not done.

Obstruction of the bowel is characterized by a colicky type of pain with comparative rest periods between cramps. The abdomen is noisy in the early case and this is characteristic. Perhaps the outstanding symptom here is the persistent vomiting in small bowel obstruction, differing from that of appendicitis where the patient vomits only a few times if at all. Surgery in these cases is imperative and prognosis will be better with careful preoperative treatment of shock and loss of fluids. A "must" in these cases is Wangensteen suction by a Levine or Miller-Abbott tube.

Hemorrhage as a cause of acute abdominal emergencies is well represented by the case of ruptured ectopic pregnancy. Other causes of abdominal hemorrhage are perforating wounds, and a rare cause is that of bleeding from cyst of the ovary. Shock in these cases may indicate excessive hemorrhage, and if shock does not improve with preoperative therapy the patient will have to be operated upon during shock, whole blood being given during the operation. Following abdominal trauma there may be profuse hemorrhage from an injured liver, spleen or mesentery. Bleeding from a spleen requires its removal while laceration of the liver may be best treated by suture or tamponade. Some patients with bleeding will have to be operated upon in shock and the mortality will of necessity be high.

The unusual case will cause the attending physician more worry, in that symptoms sometimes do not follow the usual pattern or closely parallel the symptoms of some of the more usual conditions. This will mean mistaken diagnoses fairly often, but with the history and symptoms of an acute emergency, exploration will be life saving.

The patient with acute abdominal symptoms should call a physician early. Early hospitalization and early operation should be the rule.

BOWEL OBSTRUCTION

An Analysis of 148 Cases

A. C. SKJOLD, M.D.
Minneapolis, Minnesota

IT would be fitting and proper in presenting a study on this subject to review briefly the salient factors which recently have come to our attention. The management of bowel obstruction successfully depends on the rational combination of non-operative and operative treatment.

All of us are aware of the desperate plight in which the individual who has a bowel obstruction finds himself. Our responsibility to him is urgent. It is important that we be able to decide on prompt, specific treatment and to recognize the moment when surgical intervention is indicated. The importance of the combination of non-operative and operative treatment cannot be emphasized too much.

Veal has summarized the mass of available data on acute bowel obstruction very nicely by saying, "The local lesion consists of distention of the bowel, alteration in its secretory and absorptive function, impairment of local circulation, and eventually gangrene of the involved segment of the intestine. The metabolic disturbance consists chiefly of loss of water, electrolytes, plasma, retention of nonprotein nitrogen and urea."

In the chronic type of low bowel obstruction, malignant neoplasms have been present so frequently that we automatically associate them. The metabolic changes are, of course, much slower in appearing, and the toxicity of the patient is much less in this type. More deliberate planning therefore may be used in choosing the method of relief to the individual.

We must expedite the treatment as soon as the diagnosis is made. Wagensteen and Paine, who made practical the decompression of the stomach and upper digestive tract by nasal suction, also have shown that it is one of our best procedures in the treatment of bowel obstruction. Finney emphasizes that this decompression be maintained both during and following operation.

Dehydration completely upsets the normal metabolism of the body so that death ensues if steps are not taken to combat it. A rapid loss of fluids from the body causing dehydration results when vomiting occurs, when there is loss of fluid into the peritoneal cavity, and when there is a disturbance in the secretory and absorptive mechanism of the bowel. This dehydration causes a fall in blood chlorides, a rise in nonprotein nitrogen, and an increase in the carbon dioxide content of the blood.

Much work has been done by Coller, Maddock, and their associates at Ann Arbor on the "electrolyte balance" of the body. They have shown that in the patient who cannot drink enough, fluid in the form of 5 or 10 per cent glucose in distilled water can be given parenterally. The body handles this fluid as though it were taken by mouth. The water becomes available for all purposes, and the glucose is either oxidized or stored as glycogen. The blood chlorides can easily be replaced by the parenteral administration of saline. Caution must be used as over-concentration of chlorides may be dangerous. DeWesselow has pointed out that a proper balance cannot always be determined by laboratory blood chloride determinations but that the clinical picture of the patient is important. The judicial replacement of fluids, electrolytes, and proteins therefore may be life saving in the management of bowel obstruction.

An adequate urinary output is essential. Wangensteen, White, Sweet, and Hurwitt all advocate a minimum output of at least 1,000 c.c. daily, although the seriously ill patient may require an output of 1,500 c.c. of urine in twenty-four hours. Coller recommends that no isotonic saline solution or Ringer's solution be given during the day of operation or during the subsequent two postoperative days. Isotonic or Ringer's solution may then be used after the postoperative urinary suppression has disappeared.

The kidneys are important regulators of the salt balance of the body and have been known to excrete as high as a 2 per cent concentration of salt in the urine; however, in low salt concentration of the body, only traces of salt may be found. The normal amount of salt in the body is 560 to 630 mg. per 100 c.c. of blood as determined by the blood plasma chloride concentration. The

Presented before the Minneapolis Surgical Society, April 3, 1947.

ability of the average surgical patient to handle salt is about the same as a well individual. The case is entirely different in the sick surgical patient; here the ease with which the kidney retains salt in the body increases.

The seriously ill patient loses salt by vomiting, nasal suction, prolonged sweating, diarrhea; and there is no replacement when there is no intake of food or water. It should be re-emphasized, however, that caution must be used not to overdo the replacement of salt in the seriously ill patient.

Recently the loss of plasma proteins has been a subject of much investigation. This loss is more important and apparent in the person with a chronic bowel obstruction. Previously, whole blood and plasma were our only available supply of protein. Now, several available commercial preparations like "amigen" contain all the necessary amino acids.

The management of the acutely ill patient with bowel obstruction presents different problems. The stomach and upper gastrointestinal tract must be decompressed with nasal suction. The replacement of fluids, salt, and protein is essential; and the determination of the amount necessary will depend on the time elapsed since the onset of symptoms, the level of the obstruction (whether high or low) and the amount of vomiting. Finney emphatically states that if colicky pains continue after decompression of the stomach and there has been time for even partial restoration of the fluid and electrolyte balance, immediate surgical exploration is mandatory. He also states that the average patient should be given in a twenty-four hour period a minimum of 3,000 c.c. of water, 5 gm. of electrolyte, 150 glucose, and 50 gm. protein. This should keep the patient in the proper balance.

The cases presented in this study of bowel obstruction are from Fairview Hospital during the years 1931 to 1947, and 148 consecutive cases are included in this sixteen-year period.

It has been difficult in some cases to evaluate the information available as to the actual existence of a bowel obstruction. It was decided that if the bowel obstruction was severe enough to warrant specific relief, it could be included in this series. No effort has been made actually to differentiate between a partial and complete obstruction. As a rule, however, most of the high obstructions were complete; and the low obstructions varied from partial to complete. Most of the obstructions due to malignancy were diagnosed beforehand and came to the attention of the physician because of bowel disturbances, bleeding, or change of bowel function. However, there were some patients who did not seek relief until the obstruction became complete.

TABLE I. TYPES OF OBSTRUCTION

Mechanical (Adhesions)	30
Inguinal Hernia	16
Volvulus	5

In reviewing these cases, it is convincing that our high mortality in bowel obstruction is due in part to the tardiness of the patient in seeking relief. Many of these individuals were very acutely ill on admission, some of them even approaching the moribund stage. Operative notes revealed resection of large pieces of gangrenous gut with an already established peritonitis.

The mechanical obstructions (Table I) constitute the largest group in this series, most of them caused by adhesions such as omental bands, inflammatory reactions and postoperative adhesions. There were thirty in this group.

It is surprising to find only sixteen obstructions due to inguinal hernia. We have heard it spoken of so frequently that we would expect more. Four were due to postoperative ventral hernia. Ventral and umbilical hernias each caused two obstructions, making twenty-four the total number of obstructions due to hernia. There were five obstructions due to volvulus. Intussusception caused four obstructions, three of which were reduced by operation and one by barium enema. There were three due to foreign bodies—a penny, a fecal impaction, and a large gallstone. Benign tumor of the rectosigmoid, mesenteric thrombosis, Meckel's diverticulum, and diverticulitis each caused one obstruction.

Of this series of 148 bowel obstructions, seventy-six were caused by malignancy. Most of these

were partial but varied in degree from partial to complete obstruction. Carcinoma of the sigmoid was by far the most common malignant lesion, occurring in twenty-nine cases. We found twelve carcinomas of the transverse colon. Carcinoma of the rectosigmoid occurred in eleven cases. Carcinoma of the cecum was next, with ten cases. There were five carcinomas of the descending colon and four in the ascending colon. There was one obstruction due to carcinoma of each of the following: splenic flexure, hepatic flexure, duodenum, jejunum, and ileum. These diagnoses of cancer were made by microscopic examination of the specimen, autopsy, observation at operation and x-ray examination. It is interesting to note that there were only three cases of cancer of the small bowel, and these were in different portions of the small bowel.

The operative procedures (Table II) used in the treatment of the bowel obstruction varied with the type, acuteness, locality, and duration of the obstruction. Simple reduction was resorted to eighteen times, with one death. In the two patients in whom resection following reduction was necessary, both died, a mortality of 100 per cent. In the eighteen patients in whom adhesions were liberated there were three deaths. There were only four cases of intussusception. One of these was reduced by a barium enema and the others by operation. Of six patients with volvulus, the two who required resection died.

In the treatment of obstruction of the large bowel, it is of special interest to note the application of the recent trends in large bowel surgery. Primary anastomosis in selected cases with adequate preoperative preparation has been highly successful.

The most common procedure was colostomy. There were twenty-six colostomies performed with four deaths. Seventeen ileocolostomies were performed, both two-stage and one-stage; there were five deaths. There were nine primary anastomoses with three deaths, and there were nine exteriorizations with five deaths. There were four anterior-posterior resections done. These obstructions were in the rectosigmoid junction. There were no deaths. There were two foreign bodies removed with two deaths, a 100 per cent mortality.

Of the total number of 148 cases studied, there were forty-one deaths (Table III) or a mortality of 27 per cent. Among the 130 patients operated upon, there were thirty-five deaths, a mortality of 26 per cent.

Eighteen individuals were not operated upon. There were six deaths in this group with a mortality of 33 per cent. These were cases that were thought inoperable, others refused surgery, and some were sent elsewhere for operation. There were sixty males, with nineteen deaths—a mortality of 31 per cent, compared with eighty-eight females, with twenty-two deaths—a mortality of 25 per cent. There were fifty-five high obstructions with eighteen deaths, a mortality of 33 per cent. It was found that the mortality rate was the highest in this group in other hospitals also. There were ninety-three low obstructions with twenty-three deaths, a mortality of 24 per cent. There were seventy-seven acute obstructions with twenty-six deaths, a mortality of 33 per cent. There were seventy-one cases of chronic obstruction with fifteen deaths, a mortality of 21 per cent. There were six cases in which only an exploratory operation could be done, and there were three deaths, a mortality of 50 per cent.

A table of mortality in all obstructions in relation to age has been compiled (Table IV). We find that in the total number of 148 cases, the most deaths occurred in the fifty to sixty year age group. There were thirty-seven cases with six

deaths, a mortality of 16 per cent. The highest mortality was in the eighty to ninety year age group where six of the seven patients died, a mortality of 84 per cent. In the seventy to eighty year age group there were twenty-one cases with six deaths, a mortality of 28 per cent. In the sixty to seventy year age group there were thirty-three cases with ten deaths, a mortality of 30 per cent. In the forty to fifty year age group there were twenty-five cases with seven deaths, a mortality of 28 per cent. There were only nine cases in the thirty to forty year age group with three deaths, a mortality of 33 per cent. Six cases occurred in the twenty to thirty year age group with two deaths, a mortality of 33 per cent. There were two cases in the ten to twenty year age group with one death, a mortality of 50 per cent. In the age group under ten years of age there were seven cases with no deaths.

TABLE V. MORTALITY IN BOWEL OBSTRUCTION
DUE TO MALIGNANCY
AGE COMPARISON

Age Group	80	70	60	50	40	30	Total
Cases	3	12	22	20	16	3	76
Deaths	2	4	6	3	4	1	20
Per cent	66	33	27	15	25	33	28

Table V is compiled to show the age group mortality in bowel obstruction due to malignancy. The sixty to seventy year age group had the most cases, there being twenty-two with six deaths, a mortality of 27 per cent. The fifty to sixty year age group was next, having twenty cases with three deaths, a mortality of 15 per cent. The forty to fifty year age group had sixteen cases with four deaths, a mortality of 25 per cent. The seventy to eighty year age group had twelve cases with four deaths, a mortality of 33 per cent. The eighty to ninety year age group had three cases with two deaths, a mortality of 66 per cent. The thirty to forty year age group had three cases with one death, a mortality of 33 per cent.

Table VI shows the mortality of bowel obstruction due to malignancy. In the seventy-six total cases due to malignancy, there were twenty deaths, a mortality of 28 per cent. There were seventy-two obstructions in the large bowel with nineteen deaths, a mortality of 27 per cent. There were three cases of obstruction due to malignancy of the small bowel with one death, a mortality of 33 per cent.

TABLE VI. MORTALITY IN BOWEL OBSTRUCTION
DUE TO MALIGNANCY

	Cases	Deaths	Percentage
Malignancy	76	20	28
Large bowel	72	19	27
Small bowel	3	1	33

An attempt was made to tabulate the progress of bowel obstruction management over four four-year periods from 1931 through 1946 (Table VII). It was interesting to note that there was a definite increase in the number of cases for each four-year period.

In the first period (1931 to 1934), there were only twelve cases with five deaths, a mortality of 41 per cent. Of these, there were six cases of high acute obstruction with two deaths, a mortality of 33 per cent. There were two cases of low acute obstruction with no deaths. There were four cases of low chronic obstruction with three deaths, a mortality of 75 per cent.

In the next group (1935 to 1938), there were sixteen cases with five deaths, a mortality of 31 per cent. This is a decrease of 10 per cent in

TABLE VII. COMPARATIVE MORTALITY

Four Year Periods	1931-1934			1935-1938			1939-1942			1943-1946		
	Case	Death	%	Case	Death	%	Case	Death	%	Case	Death	%
High acute	6	2	33	3	3	100	17	5	30	31	9	29
High chronic							1	0	0	10	2	20
Total	6	2	33	3	3	100	18	5	27	41	11	26
Low acute	2	0	0	1	0	0	6	2	33	11	3	27
Low chronic	4	3	75	12	2	16	20	4	20	24	6	25
Total	6	3	50	13	2	15	26	6	23	35	9	25
Total All Obstructions	12	5	41	16	5	31	44	11	25	76	20	26

mortality from the previous period with an increase of four cases. Here there were three cases of high acute obstruction with three deaths, a mortality of 100 per cent. There was one low acute obstruction with no death and twelve low chronic obstructions with two deaths, a mortality of 16 per cent.

In the third period (1939 to 1942) there were forty-four cases, an increase of twenty-eight cases over the previous four years. There were eleven deaths, a mortality of 25 per cent, a decrease of 6 per cent. During this period the use of stomach and upper gastrointestinal decompression began; also the use of sulfonamides. There were seventeen high acute obstructions with five deaths, a mortality of 30 per cent; one high chronic obstruction with no death. There were six low acute obstructions with two deaths, a mortality of 33 per cent. There were twenty low chronic obstructions with four deaths, a mortality of 20 per cent.

In the last group, comprising the years 1943 to 1946, there was a total number of seventy-six cases with twenty deaths, a mortality of 26 per cent. This is approximately the same mortality as in the previous group. During this period, in addition to nasal suction and sulfonamides, we began the use of penicillin and streptomycin. There were thirty-one high acute obstructions with nine deaths, a mortality of 29 per cent. There were ten high chronic obstructions with two deaths, a mortality of 20 per cent. There were eleven low acute obstructions with three deaths, a mortality of 27 per cent. There were twenty-four low chronic obstructions with six deaths, a mortality of 25 per cent.

The very definite increase in the number of cases from group to group would indicate that we are recognizing these obstructions, especially those of a malignant nature. We are also recognizing the advance that modern surgery has made in successfully operating on patients we previously felt were inoperable.

The definite decrease in mortality in the last two periods is indicative of better treatment. The advancements of nasal suction, sulfonamides, streptomycin, whole blood transfusion, and supportive treatment have made surgical procedures possible at the present time which were not attempted previously.

In reviewing the literature, we find frequent references to high mortality occurring in bowel obstruction following operations for acute appendicitis. This was true in our series of cases also. We had eight cases of bowel obstruction following operation for acute appendicitis in which reoperation was required. There were five deaths, a mortality of 62 per cent.

It has been suggested that better results can be obtained if we treat these patients conservatively for a longer period of time, as some of them will not need to be operated upon if their symptoms subside under decompression of the upper gastrointestinal tract, parenteral therapy, and whole blood transfusion. We must bear in mind, however, that in these cases, should the symptoms persist in spite of adequate nonoperative treatment, surgical intervention is necessary.

Summary

1. A total number of 148 consecutive cases of bowel obstruction at Fairview Hospital have been studied.

2. Of the 148 cases studied, there were forty-one deaths, a mortality of 27 per cent. Of the 130 patients operated upon, there were thirty-five deaths, a mortality of 26 per cent.

3. There was a definite decrease of mortality in each four-year period from 1931 through 1946.

4. The high mortality of bowel obstruction can be reduced by (a) the earlier presentation of the patient for treatment, (b) adequate non-operative treatment such as replacement of fluids, glucose, electrolytes, and proteins.

5. If colicky pains still persist in the abdomen after decompression of the stomach and upper gastrointestinal tract, immediate surgical exploration is mandatory.

6. Decompression of the stomach and upper intestinal tract should be established by nasal suction as soon as the diagnosis of bowel obstruction is made. This procedure should be carried on postoperatively until all distention disappears.

7. In addition to blood chemistry determination an accurate fluid intake and urinary output record is extremely valuable.

8. Defunctionalization and decompression of the colon in complete or partial obstruction of the left colon may be best accomplished by a transverse colostomy.

Discussion

IVAR SIVERTSEN, M.D.: I have enjoyed this paper very much. I do not know that I shall say a great deal about the subject. During Dr. Skjold's paper, I noted that not much was said about the use of nasal suction or the Miller-Abbott tube.

The mortality of this group of cases for Fairview Hospital has been more than average. It may be due to the fact that the patient has not been prepared before surgery, especially with the use of nasal suction or the use of the Miller-Abbott tube.

I have used the Miller-Abbott tube for some years, and in 1940 I suggested to Dr. Wangensteen that he try the use of mercury in the Miller-Abbott tube until it has passed into the duodenum. I had found it rather difficult to get it into the intestines on several occasions, but since I have used mercury in the bag of the tube, we have had less trouble. I have seen the tube pass through the gastrointestinal tract and appear in the anus when mercury was used. I also found that we can decompress the stomach with the ordinary nasal suction procedure and use the Miller-Abbott tube as well. Fluids intravenously, or subcutaneously, and transfusions of blood are certainly valuable in these cases. Preparation of the patient is most important. I think it was Dr. MacNealy who suggested the preparation of the patient very carefully with enemas, nasal suction, and even suggested small doses of mineral oil every day by mouth to soften the fecal matter in the bowel.

We must use all procedures that we can, and not only decompress the stomach but also the bowel. The patient will have to be watched carefully, and if pains continue after an effort has been made for decompression I think we had better depend on surgery to relieve the obstruction. I was just a little disappointed at the high percentage of deaths in our hospital, but hope they will decrease in the future.

O. J. CAMPBELL, M.D.: This is such an involved subject that it does not lend itself well to a brief discussion. I merely wish to compliment Dr. Skjold for undertaking this study and to suggest that it is a desirable type of study for each hospital staff to consider.

While the mortality rate which Dr. Skjold reports is high, I do not believe that it is excessively high for the period covered by the study and for the type of staff which did the operating, including as it does both trained surgeons and casual operators. Continued concern on the part of any hospital staff towards its operative results can hardly fail to influence favorably both the morbidity and mortality figures.

E. A. REGNIER, M.D.: I enjoyed hearing Dr. Skjold's paper. It takes a great deal of fortitude to critically review a large series of cases of intestinal obstruction. There seems to be a general impression that acute intestinal obstruction cannot be treated without the use of continuous aspiration of the stomach preoperatively. It is my opinion that in purely adhesive, nonmechanical obstruction occurring in the recently operated cases, one is justified in using nasal suction. However, in all cases of obvious mechanical obstruction and suspected strangulating obstruction, I do not believe nasal suction offers anything but delay in operating. A great many times this method of treatment is used in patients who have gone beyond the stage of peristaltic pain and have developed an ileus. This is apt to be most misleading. There is only one treatment for acute obstruction and that is immediate surgery. Operating on these cases should never be delayed beyond the few hours which may be necessary to rehabilitate the patient sufficiently with fluids or blood in order to render operation safe. The use of nasal suction needs a great deal of clarification before the profession, and I believe its misapplication is fraught with danger.

CLARENCE DENNIS, M.D.: I would like to say a little in support of what Dr. Regnier has said. I believe all of us agree that in the treatment of small intestinal obstructions, there is need to use nasal suction either with Dr. Wangensteen's tube or with the Miller-Abbott tube or some modification of it, but to treat small intestinal obstruction with suction and forget about the patient is a grave mistake. If conservative therapy is to be employed, one must be certain that strangulation is not occurring. The abdomen must be examined every four to five hours, white blood counts must be made every twelve hours, temperatures and pulses must be taken every four hours around the clock, and a number of other things must be done to detect the presence of strangulation early. If one is not in a position to watch the patient very closely throughout, it is better not to use conservative therapy for small bowel obstruction at all.

I am in agreement with Dr. Regnier that cessation of cramps cannot be taken as an indication that conservative therapy has been successful in the management of small bowel obstruction.

ARTHUR C. SKJOLD, M.D. (closing): The mortality of bowel obstruction we know is high, and I am aware of the desperate plight in which these patients find themselves, having observed them in the different hospitals where I have worked. Many of them come in with an early existing peritonitis, and it seems to me that the procedure in these cases depends on one's own personal

(Continued on Page 86)

EVALUATION OF LIVER FUNCTION TESTS

HAROLD H. JOFFE, M.D., and ARTHUR H. WELLS, M.D.
Duluth, Minnesota

DR. A. H. WELLS: After sixteen years of critical experience with the interpretation of the clinical significance of laboratory measurements of the various physiologic functions of the liver, we found a few tests of definite value in demonstrating (1) decreased liver cell function due to diffuse diseases of the liver, (2) mechanical obstruction of bile ducts, and (3) the progress of certain liver diseases. Other laboratory tests prove to be of no differential diagnostic value. Dr. Joffe has laboriously reviewed some of our more recent experiences with a selected group of patients.

DR. H. H. JOFFE: Liver function tests are valuable supplements but not substitutes for a carefully taken history and a thorough physical examination.[19] The present dissatisfaction with liver function tests is largely due to a tendency to rely solely upon the result of one particular test.[34] Early recognition of liver disease by means of physical findings alone is often difficult.[10] The most careful clinical history laboratory studies and the best of medical judgment often do not enable one to distinguish medical or hepatocellular from surgical or obstructive jaundice. In our experience there are several laboratory tests which, when used together, greatly increase the physician's diagnostic ability in this frequent and serious field of medical practice.

I will now present for consideration our viewpoint of the literature and our experience with the icterus index, total serum bilirubin, qualitative Van den Bergh, quantitative direct and indirect Van den Bergh, cephalin flocculation, urine and stool urobilinogen, blood cholesterol and cholesterol esters, galactose tolerance, hippuric acid test, bromsulphalein excretion test, blood proteins and liver biopsy.

Icterus Index

The normal icterus index ranges from 2 to 6 units. It is a nonspecific color comparison test which is used clinically because of its simplicity.[4] The test is a rough but practical index of the degree of bilirubinemia. Hemolysis and turbidity of the serum interfere with the color comparison. Other substances such as carotene, lipochromes, and xanthophyll may impart a yellow color to the serum, thereby increasing the difficulties in interpretation.[4,14,43] In comparison, the quantitative Van den Bergh is an accurate scientific chemical measurement of bilirubin in the blood.

There is a wide range of the blood bilirubin (when measured by any method) in the hepatocellular causes of jaundice.[39] In the obstructive types of jaundice the icterus index is usually higher in the neoplastic jaundice, the average being about 100 units. In jaundice due to calculi it is rarely above this level. However, due to a considerable overlapping, the use of this test as a reliable means of differentiation is questionable.[39]

TABLE I. ICTERUS INDEX

Units	Hepatitis	Cirrhosis	Neoplastic	Cholelithiasis	Common Duct Stone
Under 20	0	4	1	0	0
20–60	37	11	2	20	2
61–100	17	0	3	5	4
101–140	3	1	3	1	0
Over 140	0	2	8	0	3
Total	57	18	17	26	9

In our series (Table I), eleven out of seventeen cases (64.7 per cent) of neoplastic (common duct obstruction due to cancer) jaundice showed an icterus index above 100 units. In the cases of hepatitis, thirty-seven of fifty-seven (64.9 per cent) showed an icterus index of under 60 units. In the group of cirrhosis, in fifteen of eighteen (83.3 per cent) the icterus index was under 60 units. In twenty-five of twenty-six cases (96 per cent) of cholelithiasis with or without cholecystitis, the index was below 100 units, and of the common duct calculi, six out of nine or (66 per cent) showed an icterus index under 100 units.

In conclusion, the tendency for neoplastic obstruction of the common duct to produce higher degrees of bilirubinemia is similar to the findings of others. It is, however, obvious that the test cannot be used with much success for differential diagnostic purposes, but must be limited to a measurement of degree of bilirubinemia.

Quantitative Van den Bergh

The total serum bilirubin is normally below 1.0 mg. per 100 c.c.[10,26,37] The total is roughly one tenth of the icterus index.[4,14] It is below 0.5 mg. per 100 c.c. in about 75 per cent of cases.[4] Jaundice is difficult to recognize if the level is below 2 mg. per cent.[10] In a group of cases the average value of the total bilirubin was found to be 10 to 15 mg. per cent in the obstructive jaundice due to stone, with a somewhat higher average, 20 to 30 mg. per cent, in neoplastic obstruction of the common duct. Some of the highest values of 30 to 50 mg. per cent were found in the cases of acute hepatocellular and neoplastic jaundice cases.[35]

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

TABLE II. TOTAL SERUM BILIRUBIN

Condition	No. of Cases	Mg. Per Cent			
		1–5	6–10	11–15	16–20
Hepatitis	42	24	15	3	0
Cirrhosis	12	7	3	2	0
Neoplastic	13	5	4	3	1
Cholelithiasis	19	13	6	0	0
Common Duct Stone	7	2	2	1	0

twelve (70 per cent) were direct and five (30 per cent) were biphasic. Of eleven cases of hepatitis, nine (81.8 per cent) showed a positive reaction, of which seven (77 per cent) were direct and two (23 per cent) were biphasic. In six cases of neoplasm, four (66.7 per cent) gave a positive reaction, of which two (50 per cent) gave a direct and two gave a biphasic reaction.

A study of Table III will lead to the already proved conclusion that the qualitative Van den Bergh tests are

TABLE III. QUALITATIVE VAN DEN BERGH

Condition	No. of Cases	Direct	Per-centage	Indirect	Per-centage	Biphasic	Per-centage
Hepatitis	46	28	60.8	4	8.7	14	30.5
Cirrhosis	14	9	64.4	2	14.3	3	21.3
Neoplastic	13	8	61.5	3	23.0	2	15.4

Common Duct Stone	7	7.42–12.93	1.57–1.64	21.4	5.77–12.93	78.6

* In one case the indirect was 80.2 per cent of the total.

A study of Table II can lead to but one conclusion, that an accurate measurement of the serum bilirubin does not aid in differentiating various causes of jaundice. The quantitative Van den Bergh test is the choice for following small daily variations of bilirubinemia in jaundice patients.

Qualitative Van den Bergh

In the history of liver function tests there has been nothing so detrimental to the general usage of the tests as the original enthusiastic and wide acceptance of the direct and indirect Van den Bergh tests as reliable means of differentiating the "medical" from the "surgical" types of jaundice. The scientific aura which accompanied the numerous lectures, textbook discussions and bedside talks concerning the explanations of the direct, indirect, biphasic, delayed direct, et cetera reactions simply accentuated the disillusionment which followed.

The great majority of cases of obstructive jaundice were found in time to be a combination of the so-called regurgitation (direct reacting) and retention (indirect reacting) varieties[4] and pure forms of retention (indirect reacting) jaundice were rare.[30] The qualitative Van den Bergh has not proved of value in the clinical differentiation between jaundice due to diffuse parenchymal liver damage and that due to mechanical obstruction of the bile ducts.[38] The qualitative Van den Bergh may be of some value in the restricted field of differentiating hemolytic from other causes of jaundice.

In a study [34] of forty-one cases of cirrhosis, seventeen or (41.5 per cent) showed a positive reaction, of which

of very little value in differentiating the diseases with hyperbilirubinemia.

Quantitative Direct and Indirect Van den Bergh

When the first reports of the use of the quantitative measurements of direct and indirect Van den Bergh reactions first appeared in the literature, our hopes were kindled anew with the belief that we now had a practical tool for the differentiation of "medical" from "surgical" jaundice. Although one can still find references in the literature as to the value of these tests in distinguishing diffuse diseases of the liver from mechanical obstruction of the bile ducts it is obvious that their value is quite limited.[4,41]

In a study[4] of 172 cases of hepatitis, forty-one cases of cirrhosis and seventy-five cases of extrahepatic biliary obstruction, both the indirect and direct reacting bilirubin was increased in the obstruction as well as in the parenchymal group.

The results in Table IV leave no doubt in our minds as to the unreliability of these tests for differentiating causes of jaundice.

Cephalin Flocculation

The Hanger's test is a satisfactory index of the activity of parenchymal damage in the absence of hepatocellular damage complicating bile duct obstruction.[4,14] A positive reaction is apparently due to changes in the globulin fractions of the serum occurring with certain types of inflammatory and degenerative changes. It may be an index of liver cell irritation or damage rather

than a measure of the functional capacity of the liver.[8,12] It is more likely to be positive in diseases characterized by diffuse parenchymal involvement, especially cirrhosis.[2,4,9,18,24,37] Rosenberg[24] found the test of value in the early diagnosis of obstructive and parenchymatous jaundice. A negative or slightly positive reaction indicates an obstructive process and a moderate to strongly positive reaction denotes parenchymatous jaundice. Hanger[9] reported a negative or at the most a 1-plus flocculation in all of twenty-five cases of obstructive jaundice, and a moderate to strongly positive reaction in thirty-three of thirty-eight cases of hepatitis and cirrhosis. Hogland and Shanks [13] found a moderate to strongly positive flocculation in 115 of 125 cases of infectious hepatitis. Barker[2] found a moderate to strongly positive reaction in 50 to 75 per cent of 1,172 cases of hepatitis in the prodromal stage, with over 90 per cent positive in the acute icteric stage during the first weeks of the disease. In forty-seven cases of acute hepatitis without jaundice the reaction was positive in 53 per cent of cases. At the Presbyterian Hospital in New York[8] seventy out of seventy-seven cases of obstructive jaundice gave a negative reaction, while forty-eight out of sixty cases of catarrhal jaundice showed either a 3- or 4-plus flocculation.

The test is usually strongly positive in cases of cirrhosis but may be negative in the quiescent or healed stage. Therefore, a negative reaction does not exclude the diagnosis.[9] It is believed to be of prognostic value in both acute hepatitis and cirrhosis. A persistently strong positive reaction is of serious prognostic significance.[4,9,15,26] Hanger[9] found a definite correlation between the degree of flocculation, clinical course and the symptomatology in a study of forty selected cases of cirrhosis, chiefly of the alcoholic type. Some of the cases were followed three years and longer, and in seventeen cases which showed a persistently strongly positive reaction, twelve deaths occurred. In comparison, only three deaths occurred in twelve cases which showed a progressively diminishing reaction, and three in eleven cases which showed a persistently weak or negative reaction. In the same study no correlation was found between the degree of flocculation and the presence or absence of ascites. However, in the presence of jaundice and ascites or of jaundice alone, the test was rarely, if ever, negative.

Whether cirrhosis is the end of stage of fatty infiltration, or whether a fatty liver is especially more subject to damage by the unfavorable condition that may co-exist, is still a debatable question. Observations[9] however, favor the latter view, for a positive reaction seldom appears in fatty infiltration unless inflammation or acute degenerative changes are present.

If we disregard a 1-plus reaction as of no practical significance, then our series (Table V) collaborates the observation of others in that the cephalin flocculation is usually moderate to strongly positive in diseases characterized by diffuse parenchymal involvement. In our series (Table V), forty-nine of fifty-two cases (94.2 per cent) of hepatitis and thirteen of fifteen (86.6 per cent) of cirrhosis showed a 2- to 4-plus reaction. In comparison, 64.3 per cent of cases of neoplastic jaundice, 88.3 per cent of cholelithiasis and 85.8 per cent of common duct calculi showed a negative to 1-plus reaction.

Urine and Stool Urobilinogen

Normally, much of the bilirubin of the bile entering the intestines is changed to urobilinogen by bacterial action. A certain portion of this decomposition product of hemoglobin is absorbed into the portal circulation and passes to the liver where it appears to be converted to bilirubin and re-excreted into the bile. The latter part of this cycle has been termed the enterophepatic circulation of bile pigment.[4,33,34,37,39]

The urine normally contains 0 to 4 mg. per twenty-four hours, usually ranging between 0.5 to 2 mg.[37,38] It usually does not exceed 3 mg. per twenty-four hours.[10,37] The urobilinogen of the stool varies from 40 to 280 mg. per day, the average being 100 to 250 for a four-day period.[35,37,40]

Persistent absence of urobilinogen from feces and urine indicates that bile is not entering the intestines and is usually the result of complete obstruction of the biliary passages by carcinoma. However, this occasionally occurs as a result of an impacted stone in the common duct, severe acute hepatitis, or complete cicatricial stricture of the duct.[32,36,41]

In acute hepatitis and cirrhosis, the normal "resynthesis" of absorbed urobilinogen to bilirubin is interfered with, and excessive amounts of urobilinogen appear in the urine. Therefore, the presence of urobilinogen in the feces indicates the bile passages are not occluded, and excessive amounts of urobilinogen in the urine indicate some impairment of liver cell function or an associated hemolytic process.[32,36,41] The only satisfactory proof of complete biliary obstruction is very low levels of fecal and urinary urobilinogen.[25,31,41]

A study[36] of 135 cases of jaundice in hepatic disease showed that jaundice due to a stone is not accompanied by any considerable increase in the urine urobilinogen, unless complicated by acute cholecystitis, cholangitis,

TABLE VI. URINE UROBILINOGEN

Condition	No. of Cases	Negative	Per Cent	Above 4 mg.	Per Cent	Below 4 mg.	Per Cent	*Below 0.5 mg.	Per Cent

Common Duct Stone	5	2	40	1	20.0	2	40.0	2	100

* Number of cases below 40 mg. which showed a stool urobilinogen below 5 mg.

biliary cirrhosis or severe anemia. In forty-nine out of fifty-three cases (92 per cent) of jaundice due to primary or secondary carcinomatous involvement of the extrahepatic biliary tract, there was complete obstruction as shown by less than 5 mg. of fecal urobilinogen per day.[39] In a combined group of 118 cases of calculous and parenchymatous jaundice, only 7.6 per cent exhibit complete obstruction, with less than 5 mg. of fecal urobilinogen per day.[39] In the same series, in 55 per cent of cases of biliary tract carcinoma the fecal urobilinogen was less than 1.0 mg. per day, in contrast with 1.7 per cent in the combined calculous and parenchymal groups. In another series,[38] out of fifty-six cases of cancerous jaundice, exclusive of primary or metastatic carcinoma of the liver, the fecal urobilinogen was less than 5 mg. in fifty-three (96 per cent). In the same series, out of forty-nine cases of calculous jaundice and sixty-two cases of parenchymal jaundice, only five (4.5 per cent) excreted less than 5 mg. of urobilinogen per day in the feces. In 120 cases[16] of acute infectious hepatitis while the icterus was present, normal urobilinogen in the urine occurred in only 16 per cent of cases. In forty-one cases of cirrhosis, thirty-four (82.9 per cent) showed an increased excretion of urobilinogen in the urine. In contrast, only four out of six cases (66.7 per cent) of neoplastic jaundice and five out of ten (50 per cent) of hepatitis showed an abnormally high excretion.[34]

In neoplastic jaundice the urine and fecal urobilinogen are less than 0.5 mg. and 5 mg. respectively per day in 90 per cent of cases.[40]

In our series (Table VI) thirteen out of fourteen cases of neoplastic jaundice (92.7 per cent) showed a negative or a urine urobilinogen below 4 mg. In contrast, fifteen out of forty-one cases (36.3 per cent) of hepatitis and three out of ten (30 per cent) of cirrhosis showed a negative or a urine urobilinogen below 4 mg.

The stool urobilinogen (Table VII) in eleven out of twelve cases (91.3 per cent) of neoplastic jaundice was either negative or below 40 mg. Of the seven cases below 40 mg., six were below 5 mg. In the group of hepatitis, twenty-eight out of thirty-eight cases (73.6 per cent) showed either a negative value or below 40 mg. Of twenty-six cases below 40 mg., thirteen (50 per cent) were below 5 mg. In the group of cirrhosis, 62.5 per cent showed a negative value or below 40 mg., however, none of the cases were below 5 mg.

Cholesterol and Cholesterol Esters

The normal total blood cholesterol is 150 to 250 mg. per 100 c.c. of serum, with the esters comprising 60 to 70 per cent of the total.[14]

Hypercholesteremia is found in the majority of cases of uncomplicated extrahepatic obstructive jaundice. In such cases there is little or no significant alteration in the relative proportions of free and ester cholesterol.[4,37] However, hypercholesteremia occasionally occurs in mild hepatocellular jaundice, but much less frequently than in the obstructive type. In the former, the increase is usually in the free cholesterol fraction with the proportion of cholesterol esters diminished.[4,41]

A percentage proportion of esters below 60 per cent indicates a hepatocellular functional disturbance.[41]

In obstructive jaundice, there is usually a sharp rise in both the free cholesterol as well as the esters, which somewhat parallels the elevation of serum bilirubin. In contrast, there is a divergence, in the parenchymal jaundice, between the degree of serum cholesterol and bilirubin elevation.[4,32]

In acute or severe forms of hepatitis, the value for cholesterol may be decreased or normal, and the esters may diminish or disappear.[32,42] In a group of 105 cases[7] with obstructive jaundice, eighty-two (78 per cent) showed a total cholesterol of more than 300 mg. The esters were above 150 in seventy-nine (75 per cent) of the cases. Patients with obstruction of the biliary passages by carcinoma had a more striking hypercholesteremia than did those with obstruction due to a stone or stricture. In only eleven (10 per cent) of 111 cases of diffuse parenchymatous disease was the total cholesterol over 300 mg. In seventy-five (slightly over 67.5

TABLE VIII. CHOLESTEROL AND CHOLESTEROL ESTERS

Condition	No. of Cases	Total Cholesterol				Cholesterol Esters			
		Above 300 mg		Below 150 mg.		No. Below 60% of Total	Per Cent	No. Above 60% of Total	Per Cent

Common Duct Stone	6	3	50.0	3	50 0

per cent) the total cholesterol was normal or slightly decreased but the esters were definitely decreased.

In our series (Table VIII) of the combined group of hepatitis and cirrhosis totaling sixty-four cases, only five (10.4 per cent) showed a total cholesterol above 300 gm., and ten (15.6 per cent) were below 150 mg. In this same combined group of hepatocellular impairment, fifty-six (87.5 per cent) showed the cholesterol esters to be below 60 per cent of the total. In all cases of neoplastic jaundice the cholesterol esters were above 60 per cent of the total. Of the common duct calculi 42.8 per cent showed a total cholesterol above 300 mg., and 85.7 per cent showed the cholesterol esters to be below 60 per cent of the total.

Galactose Tolerance

The galactose tolerance test is based on the ability of the liver to convert this sugar into glucose. If this conversion does not take place the galactose is completely excreted in the urine.[34] In the absence of diabetes, normally less than 3 grams of the sugar is excreted in 5 hours.[4,41] Excretion of more than 4 to 5 grams is indicative of severe hepatic impairment.[4,26,41] Although a positive galactose test is almost the rule in acute hepatocellular jaundice of average severity, a negative response may occur in mild or long standing cases.[1,4,26] It may be positive in long standing obstructive jaundice because of secondary parenchymal liver damage.[1,4,26]

A normal response does not exclude the possibility of parenchymal involvment and a borderline positive test should not be regarded as conclusive evidence against the presence of a mechanical biliary obstruction.[1,41]

The test does not uniformly distinguish between obstructive and hepatocellular jaundice, but it may furnish corroborative proof in doubtful cases.[1]

At the Mayo Clinic[41] the test was found to be mildly positive in 50 per cent of malignant obstruction cases and in 25 per cent of cases of obstruction due to a stone or cicatricial stricture. A positive response may be obtained in 30 to 45 per cent of patients with obstructive jaundice of various types.[1] In sixty-five cases of hepatitis, the test was positive in sixty-one (93.8 per cent). Of twenty cases of obstructive jaundice, less than 3 grams were excreted in all cases regardless of the duration of the jaundice or cause of the obstruction.[27] However, in a group of 167 cases with a normal synthesis of hippuric acid, only 7 per cent had abnormal excretion of galactose.[6] The test is more likely to be positive with diffuse hepatitis than with cirrhosis or neoplasm.[34]

In our series (Table IX) thirty-six out of forty-two cases of hepatitis (85.7 per cent) and eight out of eleven cases of cirrhosis (72.7 per cent) showed a positive test. However, only 10 per cent of the cases of neoplastic jaundice, 38.4 per cent of the cases of cholelithiasis, and 50 per cent of cases with common duct stone showed a positive test.

Hippuric Acid

The test depends on the ability of the liver to furnish glycine to permit the synthesis of hippuric acid from benzoic acid.[4,14,41] Normally 3 grams of benzoic acid in the form of hippuric acid is excreted in the urine in four hours after the ingestion of 6 grams of sodium benzoate.

A low output of hippuric acid is strong, but not conclusive evidence of functional liver impairment.[21,26] Excretion below 3 grams indicates hepatic insufficiency, provided renal function is normal and the volume of urine is adequate.[4,26,37,41] The results of this test parallel those obtained with the bromsulphalein test in patients without jaundice.[32,41]

In two instances the test was of little value in a differential diagnosis as it showed some degree of reduction in practically every type of liver disease.[21,25]

The oral hippuric acid test shows practically no correlation with the clinical condition of the patient. It is frequently relatively low in the convalescent period from infectious hepatitis, and even after the oral administration of amino acetic acid in the form of gelatin just prior to the test, normal excretion occurred in 153 out of 156 cases.[2] In a study[6] of 381 patients with suspected liver disease, 167 (43.9 per cent) showed a normal excretion of 3 grams or more: 134 (35.9 per cent)

showed 2 to 3 grams; forty-nine (12.8 per cent) showed less than 1 gram in the urine.

In a group of non-obstructive jaundice, including acute hepatitis, metastic carcinoma of the liver and cirrhosis, 89 per cent of forty-six cases, using the intravenous route, and 52 per cent of nineteen cases, using the oral route, showed a positive test. In forty-seven cases of proven cholelithiasis the intravenous test was positive in 53 per cent, as compared to 6 per cent of fifteen cases in which the oral test was used.[17]

The test was found to give low results in cases of catarrhal jaundice, acute and chronic hepatitis, usually in cases of liver metastasis and in cases of cirrhosis. Normal results are obtained in uncomplicated cholecystitis and cholelithiasis, including obstruction, as the result of a stone in the common duct.[21,22,23] The test is thought to be valuable in differentiating between intrahepatic jaundice from that due to obstruction by a stone in the common duct. However, an obstruction of long duration as well as carcinoma of the head of the pancreas may lead to liver cell damage and therefore, give low results.[23]

In one study[4] the hippuric acid excretion was less than 2.5 gm. in 91 per cent of 270 cases of hepatitis, in 87 per cent of seventy-six cases of cirrhosis, in 63 per cent of 136 cases of common duct stone and in 43 per cent of sixty-seven cases of carcinoma of the pancreas.

In our series (Table X), using the oral test, the excretion was less than 3 grams in 81.6 per cent of cases of hepatitis, in 80 per cent of cirrhosis and in 60 per cent of common duct stone. However, the results were 3 grams or above in 70 per cent of neoplastic jaundice and in 63.6 per cent of cholelithiasis.

TABLE X. HIPPURIC ACID

Condition	No. of Cases	Less Than 3 Gm.	Percentage	3 Gm. or More	Percentage
Hepatitis	38	31	81.6	7	18.4
Cirrhosis	10	8	80.0	2	20.0
Neoplastic	10	3	30.0	7	70.0
Cholelithiasis	11	4	36.4	7	63.6
Common Duct Stone	5	3	60.0	2	40.0

Bromsulphalein

This test appears to be a measurement of the excretory function of the liver. Normally not more than 10 per cent of the dye is retained in the blood thirty minutes after administration. Not more than 5 per cent remains in the blood at forty-five minutes and none after one hour.[37,41]

The test is fairly delicate in detecting liver dysfunction in the absence of jaundice, but is generally positive in the presence of an icterus index greater than 20 units or a serum bilirubin greater than 2.0 mg. per 100 c.c.[4,10,1432,37,41] A positive test indicates some degree of liver injury but a negative test does not rule it out.[34]

In the presence of complete obstruction of the common bile duct, the degree of retention of the dye in the blood increases progressively with that of bilirubin. Therefore, this test gives us very little information that cannot be obtained by the quantitative serum bilirubin.[4,14] However, incomplete obstruction, with superimposed chronic biliary tract disease and hepatocellular damage, may show a retention of the dye out of proportion to the degree of hyperbilirubinemia. It is, therefore, of value in the preoperative study of patients with cholelithiasis.[4,14]

TABLE XI. BROMSULPHALEIN

Condition	No. of Cases	No. of Positive	Percentage
Hepatitis	26	17	65.3
Cirrhosis	7	4	57.0
Neoplastic	6	3	50.0
Cholelithiasis	8	3	37.5
Common Duct Stone	3	2	66.0

Abnormal retention occurs almost invariably in acute and chronic disease due to hepatocellular damage, the degree of retention being roughly indicative of the extent of hepatic functional impairment and usually parallels the degree of hyperbilirubinemia. As in the case of obstructive jaundice, abnormal retention of dye may occur before and may persist longer than the hyperbilirubinemia.[4,14]

Retention of dye occurred in 96 per cent of cases in which there was evidence of parenchymal hepatic injury or even moderate mechanical obstruction of the bile ducts which had not yet produced clinically demonstrable jaundice.[32]

In a study of seventy-six cases[3] with active chronic hepatitis that failed to recover completely from acute infectious hepatitis, the bromsulphalein test was found to be the most valuable. In this series, 64 per cent of forty-four cases in the nonicteric group and 69 per cent of twenty-six cases in the icteric group, for an average total of 66 per cent, showed an abnormal retention of dye. In comparison, only 47 per cent of forty-seven cases in the nonicteric group and 76 per cent of twenty-nine cases in the icteric group, for an average total of 58 per cent, showed an abnormal cephalin flocculation.

The test was positive in nine of eleven cases (81.8 per cent) of common duct stone and in all of five cases of neoplasma.[27] The test was also positive in thirty-seven of forty-one cases (90.2 per cent) of cirrhosis, in nine out of ten cases (90 per cent) of hepatitis, and in all of six cases of neoplasm.[34] In 42 per cent of fifty-two cases of proven cholelithiasis the test was likewise positive.[17]

In another series[4] the retention of dye occurred in 80 per cent of 270 cases of acute hepatitis, in 68 per

TABLE XII. SERUM ALBUMIN

Condition	No. of Cases	Below 4 gm.	Percentage
Hepatitis	19	4	21 0
Cirrhosis	13	8	61 6
Neoplastic	9	4	44 4

cent of seventy-six cases of cirrhosis, and in 100 per cent each of 136 cases of common duct stone and 67 cases of carcinoma of the pancreas.

In our series (Table XI), 65.3 per cent of cases of hepatitis and 57.7 per cent of cirrhosis showed an abnormal retention. In comparison, 50 per cent of cases of neoplastic jaundice, 37.5 per cent of cholelithiasis, and 66.6 per cent of common duct calculi showed an abnormal retention.

Serum Protein

The protein of serum is normally 6 to 8 grams per 100 c.c.[4,14,,41] The serum proteins are usually altered in chronic diffuse liver disease with a reduction chiefly in the albumin fraction and an increase in the globulin. There is often a reversal of the albumin-globulin ratio, which is an important factor in the production of edema and ascites.[4,34,37,41] Total values as low as 3 grams per 100 c.c. have been reported in cirrhosis. The increase in the globulin fraction is more pronounced in chronic hepatocellular disorders than in biliary obstruction, which is usually not accompanied by a decrease in the serum albumin unless it is of long duration. However, a reduction in the serum protein is sometimes seen in acute hepatitis and chronic passive congestion.[4]

The serum albumin was less than 4 gm. in 30 per cent of 270 cases of acute hepatitis, in 63 per cent of seventy-six cases of cirrhosis, in 70 per cent of fifty cases of congestive heart failure, in 69 per cent of 136 cases of common duct stone, and in 79 per cent of sixty-seven cases of carcinoma of the pancreas.[4] The albumin concentration was under 4 gm. in thirty-three of forty-one cases (80.5 per cent) of cirrhosis.[34]

In our series (Table XII), the serum albumin was below 4 gm. in four out of nineteen cases (21 per cent) of hepatitis, in eight out of thirteen (61.6 per cent) of cirrhosis, and in four out of nine (44.4 per cent) of neoplastic jaundice.

Liver Punch Biopsy

The addition of liver biopsy to laboratory tests affords an unparallel means of correlating functional with histologic changes. The value of this procedure in the differential diagnosis of jaundice cannot be overemphasized, and in equivocal cases of diffuse diseases such as hepatitis and cirrhosis an absolute diagnosis can be made.

The manifestations of cirrhosis are so varied and so often preplexing that the clinician needs all available aids in making a diagnosis.[12]

The danger of death from hemorrhage should not be a stumbling block in the routine performance of this procedure, providing the prothrombin, clotting and bleeding times are checked prior to the procedure. There are only twelve deaths reported in the literature ascribed to needle biopsy, and most of these occurred during the early days of trial of this procedure.[11]

At the University of Minnesota needle biopsy had been attempted in eighty cases since October, 1942,[11] and was found to be of great value in the clinical study of liver diseases as well as a great diagnostic aid.

One can expect reasonably good results in cases of cirrhosis and acute hepatitis. However, it is conceivable how a carcinoma nodule might be by-passed.[11,12,28]

In our series of fourteen cases in which a clinical diagnosis of hepatitis was made, the liver biopsy diagnosis did not confirm the clinical diagnosis in six (42.8 per cent), primarily due to inadequate biopsy material. The diagnosis of cirrhosis by biopsy in ten cases was confirmed by autopsy in all cases. In eight cases clinically diagnosed as carcinoma, a liver biopsy confirmed the clinical diagnosis in only three (37.5 per cent).

Conclusion

Our broad statistical study of the various liver function tests does not show their true usefulness. When many other factors of the clinical history and physical findings are taken into account, the efficacy of some of the tests in differentiating "surgical" from "medical" jaundice is greatly increased. Using our figures, which check closely with those found in the literature, one can see the value of multiple tests. If, for instance, the cephalin flocculation test is 75 per cent accurate, add to this the roughly similar accuracy of several tests and the end result of the combination will be well worth the effort of running the series. A long experience in the interpretation of the results of these tests is indeed valuable. Tests other than those we have reviewed, including the thymol turbidity, alkaline phosphatase and the duodenal drainage, have proved their place in this difficult field of medical diagnosis.

Studies of the blood bilirubin are useful in determining the amount and progress of bile retention. Any attempt at using the various Van den Bergh tests for differentiating the diseases with jaundice is subject to too much error and should be discouraged.

The cephalin flocculation test is a fairly reliable means of differentiating diffuse parenchymal damage from that due to an obstruction of bile ducts. In our series, forty-nine of fifty-two cases (94.2 per cent) of hepatitis and thirteen of fifteen (86.6 per cent) of cirrhosis showed a 2- to 4-plus reaction. In comparison, 64.3 per cent of cases of neoplastic jaundice, 88.3 per cent of cholelithiasis, and 85.8 per cent of common duct calculi showed a negative to 1-plus reaction.

Very low levels of urine and fecal urobilinogen are satisfactory proof of complete biliary obstruction. In our series of neoplastic obstructive jaundice, 92.7 per cent showed a urine urobilinogen that was negative or below 4-mg. and 91.3 per cent showed the stool urobilinogen to be either negative or below 40 mg. However, 36 per cent of forty-one cases of hepatitis had a negative or below 4 mg. per cent level of urobilinogen.

Hypercholesteremia, above 300 mg. per 100 c.c., is frequent (42.8 per cent) in cases of common duct cal-

culi, while only 10.4 per cent of the combined group of hepatitis and cirrhosis have a total blood cholesterol above 300 mg. Blood cholesterol ester levels must be interpreted with much caution. When they fall below 20 or 30 per cent of the total cholesterol, diffuse disease of the liver is indicated especially when successive tests reveal a continuous drop. Small decreases of the ester below 60 per cent of the total are of no significance as a differential test.

In our combined series of hepatitis and cirrhosis, the galactose tolerance test was positive in 86.6 per cent of cases, as compared to 10 per cent of cases of neoplastic jaundice, 38.4 per cent of cholelithiasis, and 50 per cent of common duct stone.

Using the oral test, less than 3 grams of hippuric acid was excreted in the urine in 81.6 per cent of cases of hepatitis, 80 per cent of cirrhosis and 60 per cent of common duct stone, while in neoplastic obstruction of the common duct and cholelithiasis, 70 and 63.6 per cent respectively showed an excretion of 3 grams or more. The intravenous hippuric acid test may be a means of increasing the diagnostic laboratory accuracy.

The bromsulphalein excretion test has its use limited to the detection of liver cell disfunction in the absence of jaundice. The results of our short series of studies of blood proteins confirms the usually accepted interpretation of this test.

When a dependable method of preventing bleeding from the site of a liver punch biopsy is found, this test will be the best for demonstrating diffuse diseases such as hepatitis and cirrhosis.

History of Medicine In Minnesota

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from December issue)

Milton A. Trow, the youngest child of Dr. Augustus Howland Trow, was born at Montezuma, New York, on May 10, 1853, and came with his parents and his two brothers, Henry Nathaniel and Willam Howland, and his one sister, Ellen Acenith Trow, to Chatfield, Fillmore County, Minnesota, in 1856 when he was about three years old. In Chatfield he grew up, received his early education and spent much of his life. His wife was May E. Dann, to whom he was married in Chatfield on December 18, 1876, the daughter of Mr. and Mrs. Amos D. Dann, originally of Chatfield, later of Jackson, Minnesota.

In 1876 Milton Trow was graduated from the College of Physicians of Keokuk, at Keokuk, Iowa, and began the practice of medicine in association with his father in Chatfield and a wide surrounding territory in Fillmore and Olmsted Counties. In the following year there were in the county three Drs. Trow, when William H. Trow, newly graduated from the same medical school at Keokuk, began his medical practice, not in Chatfield, but in the village of Fillmore, some miles to the southeast.

Early in his professional career Milton Trow, newspaper notices would indicate, began lecturing on anatomy, physiology and phrenology in villages of the two counties. As has been noted, he was one of the physicians of the late seventies who co-operated with the State Board of Health in the preparation of reports on local conditions of health and sanitation; and in 1880 he was appointed county physician in Elmira and Orion Townships of Olmsted County. Under the "Diploma Law" of 1883 he became the possessor of state certificate No. 874 (R), given on April 19, 1884, filed in Fillmore County on September 14 of that year. By then he was announcing himself in a professional card as a physician and surgeon who would attend to all professional calls, day or night, promptly. And in 1884, concerned with farming as well as with medicine, he advertised "a lot of 90 day yellow dent corn for sale."

There occurred in 1883 an incident in his medical practice that was disagreeable but that ultimately did him no harm and perhaps was helpful. The fact that Dr. Franklin Staples, of Winona, was called in consultation in the case concerned and that a letter from Dr. Staples to Dr. Augustus H. Trow subsequently was published in the *Chatfield Democrat* on March 10, 1883,

at the request of the senior Dr. Trow, "for the especial benefit of those who prefer to spread false reports rather than the truth," lends interest. The letter follows:

Winona, February 24, 1883.

I attended the late Mr. ————————in consultation with Dr. M. A. Trow on Saturday the 19th inst. In my opinion the patient was suffering from a complication of diseases, in which the liver and right lung were involved. I think there was and had been for some time, a pneumonia in the posterior lobe of the right lung, also enlargement of the liver and threatened hepatic abscess. I thought the treatment in the case had been and was good. I advised its continuance in the main and suggested the use of nitro muriatic acid. I spoke openly and plainly and gave the above opinion both to Dr. Trow and to the friends by themselves, and have not expressed any other opinion, nor had any other to express. The treatment was the same I should have given. I regarded the prognosis of the case as extremely unfavorable.

Beginning in the early eighties Dr. Augustus H. Trow and Dr. William H. Trow became increasingly interested in the agricultural properties which they had acquired in Dakota Territory and in 1887 they went west to settle in the new country. After their departure Milton Trow practiced alone from his headquarters in Chatfield, and in the ensuing twelve years he greatly extended his work. In 1892 he had established branch offices in Olmsted County, one at the Russell House in Pleasant Grove and one at the Everett House in Eyota, in each of which he spent one day a week. It was during this period also that he achieved his well-earned reputation as an able obstetrician, receiving praise from Dr. J. B. McGaughey, at a meeting of the Winona County Medical Society: "Over fifteen years' practice without a fatal case or having to be helped is a record of which any man might be proud." (*Chatfield Democrat,* October 16, 1892.)

In the winter of 1893, perhaps then in the period of his heaviest professional activities, Dr. Trow on a night in early March, when the roads were almost impassable, was injured severely about the head and shoulders when his cutter overturned. Already in a state of extreme fatigue (judging from detailed newspaper accounts of certain incidents in his practice), after the accident for many weeks he was seriously ill, having received a concussion of the brain, and was the subject of medical consultation to which were called Dr. J. P. Waste, of Plainview, Dr. A. W. Stinchfield and Dr. W. A. Allen, of Rochester, and Dr. C. McH. Cooper, of Chatfield; Dr. A. H. Trow had come from Dakota. Not long afterward, on the advice of his physicians to go somewhere "where absolute quiet and freedom from visitors and business could be obtained," Dr. M. A. Trow and his wife and their little daughter, Ruth, went to Jackson, Minnesota, for a period of his convalescence, to stay with Mrs. Trow's parents.

It was a year or two later, when relatives were hoping that Dr. Trow would settle permanently in Jackson, that friends in Chatfield sent to the editor of the *Chatfield Democrat* for publication a sincerely eulogistic set of reasons why they would "dislike to have him go." He was, they said, a man of good moral character, a good citizen, a true Christian gentleman. As an able practitioner and a completely successful surgeon for more than twelve years, he was greatly in demand. He stood at the head of his profession as president of the Fillmore County Medical Society, was an officer and an active member of the Olmsted County Medical Society and an honorary

member of the Winona County Medical Society. He had done more to elevate the standards and maintain the dignity of the medical profession than any other man in southern Minnesota. His worst fault was that he was a poor collector and that he did too much charity work for his own good (his generosity being "inherited from his father"). "We could get 2,000 signatures on petition requesting him not to go. We know that family ties are strong, but we hope the Doctor will not leave us." Dr. Trow did remove to Jackson, however, although not until late in the nineties. In the meantime, in 1894, Mrs. Trow was seriously ill; in that year also Dr. Trow was offered, but did not accept, a post as district surgeon of the Chicago and Northwestern Railroad, and it was stated, again in the local *Democrat*, that he had two opportunities to join medical firms in Winona.

It was in the nineties and soon after the turn of the century that Dr. Trow was most active in the work of medical associations. On June 19, 1890, at the twenty-second annual meeting of the organization, he was elected to membership in the Minnesota State Medical Society, and in 1892, when the Southern Minnesota Medical Association was organized at Winona, on July 28, he was one of the charter members and was elected second vice president. It is interesting to note that at the initial meeting Franklin Staples, of Winona, was president; Nathaniel S. Tefft, of Plainview, first vice president, and Horace W. Witherstine, of Rochester, secretary and treasurer. Dr. Trow's name continued on the roster through 1897. After moving, probably in 1899, from Chatfield to Jackson, in Jackson County, he was affiliated with the Jackson County Medical Society, as witness the following item which appeared in the *Northwestern Lancet* in February, 1901: Dr. M. A. Trow of Jackson, Minnesota, contributed a very sensible article in the form of a letter, to a local paper on the subject of physicians' fees. Dr. Trow, as president of the Jackson County Medical Society, which voted unanimously for the common country fee schedule, was charged with forming a trust. Dr. Trow will never suffer much from such a charge in or out of Jackson County."

In May, 1902, it was announced in the *Northwestern Lancet* that Dr. M. A. Trow, formerly of Chatfield, Minnesota, had located at Lamberton, Redwood County, and had formed a partnership with Dr. Crandall of that place. Evidently the arrangement was of short duration, for in March, 1903, Dr. Trow, recently of Currie, in Murray County, had removed to Avoca, a few miles south in the same county, and there he remained until after 1917; in the issue for 1918 his name appeared for the last time in the directory of the American Medical Association, followed by the symbol for "Address Unknown.".

In these later years his health had begun to fail and in the next half decade he carried on but a desultory medical practice. He finally returned to his old home of Chatfield, to be among the associations of early years, although no member of his immediate family then was residing in the village. His wife had died some years previously; of the three children, two had died in infancy and the third, Ruth, lived to the age of only sixteen or eighteen years. A little story concerning those children has come down through reminiscent channels. On an occasion when Ellen Acenith Trow Bibbins was visiting her brother in Chatfield, when he was a young physician, Ruth, then a very small girl, was gaily pounding her chair with her silver drinking cup. "Mit," said the sister, "she will spoil that chair and cup." To which Dr. Trow replied, "I hope she does. We have had two

little ones leave us without a scratch to know they had ever been here, and if she goes, I want something as a reminder."

Toward the end of his life, no longer practicing medicine, Dr. Trow closed his office in Chatfield, which for a time he had maintained in the building of the Root River State Bank; in those terminal months the Chatfield Meridian Lodge of the Masons gave him the fraternal aid and care of which he was in need.

Milton A. Trow, who lives in the kindly memories of his old friends and associates, died suddenly in Chatfield on March 16, 1923. He was survived by his sister, Ellen Trow Bibbins, who then was living in Tulsa, Oklahoma; Mrs. Bibbins, who was married to Edward Bibbins, of Chatfield, on July 26, 1864, died in Tulsa at the home of her only child, Zilla Eulalie (Mrs. Samuel Alexander) Patrick, on February 18, 1936; Mr. Bibbins had died in Chicago in 1902. The eldest of the Trow brothers, Henry Nathaniel, had died in Des Moines, Iowa, on January 31, 1908. Notes on Dr. William Howland Trow follow this sketch.

William Howland Trow, the second of three sons and the third of the four children of Dr. Augustus Howard Trow, was born at Victory, New York, on August 8, 1851, and was about five years old when the family settled in Chatfield, Fillmore County, Minnesota, in the summer of 1856.

With his sister Ellen Acenith and his brothers Henry Nathaniel and Milton Augustus, William H. Trow went to school in Chatfield. In due time he received his formal medical training at the College of Physicians and Surgeons of Keokuk, Iowa, from which he was graduated on February 13, 1877, a year after Milton Trow had taken his degree at the same school. Before he began his medical study, William Trow had been married to Agnes M. Simpson, of Chatfield, on December 25, 1872. When he returned to Fillmore County from Keokuk, he settled with his family in Fillmore Village and there and in Wykoff he carried on his medical practice until he moved to Dakota Territory with his father in 1887. In Minnesota, on April 19, 1884, under the medical practice act of the preceding year, he received state license No. 916 (R), and his father and brother were licensed on the same day. And in Dakota, on July 11, 1887, both he and Dr. A. H. Trow, then residents of Carthage, Miner County, were licensed to practice in the territory. As noted previously, Dr. Augustus A. Trow had owned land in Dakota since the early eighties and it is probable that both he and William Trow had spent considerable time in the territory before they finally left Minnesota.

Dr. and Mrs. William Howland Trow were the parents of seven children, of whom the eldest two died in infancy; the others were Maude, Nina, Edith, Charles and Halcy. In the years at Carthage the family was affiliated with the Episcopal Church of Howard, South Dakota.

In 1901, Dr. Trow, accompanied by his immediate family and his father, moved from Carthage to Ethan, South Dakota, where he continued in active medical practice for about ten years. As noted, his mother had died in 1898 at Carthage; his daughter Maud (Mrs. Mack) died in 1902; his father died at Ethan in 1904. Early in 1920 Dr. Trow was ill for two months from cardiac disease; a stroke of paralysis hastened his death, which occurred ten days later, on April 5, 1920. He was survived by his brother and his sister Ellen; his wife, two sons, Charles S. and Halcy C. Trow, and one daughter, Mrs. Nina Oatbout, all of Ethan; one daughter, Mrs. Edith Swartz, of Parkston, South Dakota; and six grandchildren.

Herbert Eugene Twitchell, son of one of Chatfield's earliest and most respected pioneer physicians, mistakenly was said (in a Minnesota medical journal in 1929)* to have practiced medicine for many years in Chatfield. In correction, and as part of his father's story, a brief sketch of his life is given here.

Herbert Eugene Twitchell, the first white child native to the village, was born in Chatfield, Fillmore County, on March 27, 1855, the son of Dr. and Mrs. Refine W. Twitchell. With his sisters, Sarah Edna, Carpie and Martha Arnold (his only brother, Steven, died in infancy) he received his early education in the schools of Chatfield, attending some of his classes in the stone building that had housed the Chatfield Academy in its short but honorable span. After his graduation from the Chatfield schools, he was a student at the Winona Normal School and thereafter taught school for a while before beginning his medical training at the Louisville (Kentucky) Medical College. From Louisville he was graduated in 1877, the winner of a scholarship, and shortly afterward began the practice of medicine in the little village of Darrtown, Butler County, Ohio. In 1882 Dr. Twitchell took postgraduate work at the Miami Medical College, Cincinnati, from which he received a degree, and in 1885 studied at the Cincinnati General Hospital. On April 18, 1886, he opened an office at Hamilton, also in Butler County, where he resided and followed his profession until a few years before his death.

During the Spanish-American War of 1898 Dr. Twitchell was appointed a surgeon of the First Volunteer Infantry of Ohio, with the rank of captain, and so served until the end of the war. In 1915 he was named surgeon of the Central Branch of the National Military Home at Dayton, Ohio, but did not accept the position. He was a member of the Sons of the American Revolution and of the Military Order of the Loyal Legion of the United States Army, which is composed of the sons of officers of the Armies of the United States.

In 1878 Herbert E. Twitchell was married to Carroline A. Spencer, of Louisville, Kentucky, and of this union one child was born, Anna Spencer Twitchell. A second marriage, to Elizabeth Deuscher, of Hamilton, Ohio, took place in June, 1896; the only child was Herbert D. Twitchell, who died at the age of thirty years, from pneumonia, leaving a wife and two sons.

Dr. Twitchell died at the Dayton Military Home on March 4, 1929. Of his immediate relatives there were living in 1943 his daughter, Anna Twitchell (Mrs. Dwight S.) Person and his sister Arna (Martha Arnold; Mrs. W. J.) Broome, both of Los Angeles, and three grandsons, all in the armed forces; Dwight S. Person, Jr., Herbert Deuscher Twitchell and John Lee Twitchell. Anna Twitchell Person has gained some prominence as a writer of verse for leading periodicals throughout the country; her facility, she has said, has come down to her from her grandfather, Dr. Refine W. Twitchell, who wrote good verse, and from an uncle, John Weekes.

Herbert E. Twitchell, without pretension to writing, produced some verses in honor of Chatfield which were published in the *Chatfield Democrat,* in 1880, and because they concern the village and scenes familiar to many of the physicians mentioned in this account, a few lines are appended:

*Journal-Lancet, May, 1929, page 216.

Dear old Chatfield—how I love thee!
How I love thy very name —
How thine image comes before me,
Pictured out within my brain.
***
There's the mill and there's the meadow;
There's the creek and there's the pond;
There is dear old Root River,
With the woodland just beyond.
***
Dear old Chatfield! How I love thee!
Though far away my lot is cast,
How I hope in years that follow
To return to thee at last.

Refine Weeks Twitchell was born at Weybridge, Addison County, Vermont, on March 29, 1823, the son of Quaker parents, Jonas and Sarah Twitchell. Jonas Twitchell, son of Daniel Twitchell, was descended from old colonial stock; his first ancestor in America was Benjamin Twitchell, a founder of Dorchester, Massachusetts, one of two brothers who came from England to New England in 1630. Refine W. Twitchell was proud of the fact that his grandfather, Daniel, was an American soldier in the American Revolution, answered the call at Lexington, was wounded at Bunker Hill and was with Washington during the memorable winter at Valley Forge; Daniel Twitchell's Documentary War Record from the Revolution is cherished by the Twitchell family as one of its choicest treasures.

When Refine Twitchell was ten years old, his parents moved to Michigan and settled in Somerset, Hillsdale County. It was there that the boy completed his preliminary education and in due time decided to fit himself for the profession of medicine. In a biographical account in the Fillmore County History of 1882 it was stated that the young man began his medical study in 1845, at Dexter, Illinois; it may have been, however, at Dexter, Washtenaw County, Michigan, not far from his home and only a few miles northwest of Ann Arbor.

Because Refine W. Twitchell was an early student (1851-1852) at the Medical School of the University of Michigan and because he was one of the earliest representatives of the school to practice medicine in southern Minnesota, space is given here to suggest the details of his medical education. Michigan was the first pioneer state to recognize the importance of professional education in medicine. When the medical school was opened at the University of Michigan, in 1850, there was specified in its official announcement that its course of instruction was to run from the first Wednesday in October to the third Wednesday in April and was to consist of lectures, quizzes and a short course in anatomy. (This was, in fact, the curricular menu of all medical schools in the country at that time.) Its endorsement of the preceptor system, which was long to remain in use, was stated in the requirements for entrance: The student must present satisfactory evidence, first, that he had pursued the study of medicine and surgery for the term of three years with some respectable practitioner of medicine;† second, he must be of good moral character and also of such literary attainments as had been recommended by the National Medical Associ-

†In 1855, in emphasis of the value of preceptorship, the school in its annual announcement stated that "clinical instruction, it is believed, is far better imparted in the walks of private practice, especially in that section of the country where the student was to locate himself, than can be done even in the best regulated hospital. The hasty walks through the wards of a hospital furnish at best but a sorry substitute for the close and accurate study of cases as they occur in the professional rounds of the private practitioner."

ation, as follows: "A good English education, the knowledge of Natural Philosophy, the Elementary Mathematical Sciences, and such an acquaintance with the Latin and Greek languages as would enable the student to appreciate the technical language of medicine and read and write prescriptions." For graduation the student must have attended the full courses of lectures, the last of which must have been in the Medical Department of the University of Michigan; he must have submitted to the faculty an original thesis in his own handwriting on some medical subject; and he must have passed an examination, held at the end of the study, satisfactory to the faculty.

On completion of his work at the University of Michigan, in 1852, Dr. Twitchell began his practice of medicine in Somerset, his childhood home. On May 23 of that year he was married to Martha Jane Carpenter, of Albany, New York, who was born at Greenville, New Hapmshire, on April 6, 1831. Early determining to move westward, Dr. and Mrs. Twitchell, in 1854, with their infant daughter, Sarah Edna, only a few months old, traveled into Minnesota Territory and settled in Chatfield, a fledgling village which had been platted in the spring of 1854 and which lay in both Fillmore County and Olmsted County. And there, with a few fellow pioneers in a sparsely settled region, they met the adventures, discomforts and hazards of frontier life. Dr. Twitchell was the first physician in Chatfield Township of Fillmore County and also in Orion Township, Olmsted County.

In Chatfield, Dr. Twitchell, who was a man of ability and versatility, and many of the pioneer physicians possessed these qualities, engaged in various occupations which he found desirable or, perhaps, expedient, because on the frontiers in the fifties and later, conditions were such as to make the practice of medicine inadequate as a source of income. His professional card appeared in the first issue of the *Chatfield Republican*, on October 25, 1856: "Refine W. Twitchell, M.D., Physician and Surgeon. Will be found in his office on Main Street at all times except when absent professionally. Particular attention paid to surgery and diseases of women and children." And in the same autumn he had a card in the newly established *Chatfield Democrat* also, and continued thereafter to insert varied announcements in the two newspapers. By 1858 he found it necessary to act as pharmacist as well as physician and surgeon, and on the corner of Main Street that later was to be occupied by Easton's Bank, stood Dr. Twitchell's drugstore, the first in Chatfield. The building was constructed of logs and housed the shop in front, and in the rear, the physician's residence. In this house, on March 27, 1855, was born Herbert Eugene Twitchell, the first white child native to Chatfield Township, and in the next four years were born there Steven (who died in infancy) and Carpie, and in the later sixties Martha Arnold ("Arna").

By the summer of 1859 Dr. Twitchell's enterprise had expanded. His announcement of August 13, in the *Chatfield Democrat* was ethical and acceptable in the established tradition of the time for a physician-druggist:

R. W. TWITCHELL, M. D.
Dealer in
Drugs and Medicines
Paints, Oils and Chemicals, Pure Wines, and
Liquors for Medical Purposes. Trusses and Braces.
STRYCHNINE
A variety of Fancy and Toilet Articles
Particular attention paid to office prescriptions. Surgical operations performed at office and elsewhere.

It perhaps was in this shop* as a laboratory that he investigated the medicinal value (which he questioned) of oil from rattlesnakes.

In separate notices Dr. Twitchell, who was a skilled orchardist, announced that trees were available. And he early manifested interest in the land, for his name on old topographical maps indicate that R. W. Twitchell was the owner of tracts in various parts of Fillmore and Olmsted Counties, and it is said that in the archives of long-established law offices his name may be seen on many legal documents relating to the transfer of property.

That Dr. Twitchell was interested in educational progress is evidenced by the fact that when the Chatfield Academy was incorporated on February 25, 1856 (it was organized on May 29, 1856), he was one of the thirteen trustees and one of the executive committee of three. The academy, after its preliminary months, was housed in its own building, three stories high and of native stone, which stood on the south corner of block 27, just across the street from Dr. Twitchell's residence on the east corner of block 38; as was pointed out to the writer, the peculiarity of this description is owing to the fact that the original plat of Chatfield was laid out northwest and southeast, parallel to the bluff which flanks the village. The academy functioned for several years, an excellent educational institution known over a large region, until it was superseded by the schools of the state. In addition to his work for the academy Dr. Twitchell served also on the village school board, in 1855 and 1856 and again in 1860 and 1861.

During the Civil War Dr. Twitchell enlisted, in August, 1862, in the Ninth Minnesota Volunteer Regiment of Infantry, which was organized in the nation-wide response to the President's call of July 2 of that year for additional troops (300,000 men). On September 18 the regiment was announced officially to contain Companies A to K inclusive, with Charles W. Le Boutellier as surgeon and Refine W. Twitchell as first assistant surgeon. Dr. Twitchell was mustered in on October 6, 1862. In July, 1864, he was promoted to surgeon of the Seventy-second Colored Infantry and in that capacity served until the close of the war. Records have revealed that he thereafter served in army hospitals in the Department of Ohio until 1866 and that in this final period he was in charge of hundreds of cases of smallpox during an epidemic of the disease in virulent form. His vigilance and skill in the care of his patients were such that he saved them all and sent them out unmarked by scars of the disease. When he returned to Chatfield in the summer of 1866, Dr. Twitchell brought with him a black boy named Web, who had been assigned to him in the army as chore-boy and general factotum and who in Chatfield aroused great interest, inasmuch as he was the first Negro the children and even many of the adult residents of the village had seen. At the beginning of the Civil War Dr. Twitchell had in progress the building of a new, and, for those times, pretentious residence, a house of ten rooms; during his absence in the army Mrs. Twitchell supervised its completion. For many years the family occupied this home; in later times it once was occupied by Dr. Florence J. Halloran and once by Dr. Charles McH. Cooper. It was still known, in 1943, as "the Twitchell place."

At home again, in 1866, Dr. Twitchell, on resuming his medical practice, published the following notice: "MEDICAL AND SURGICAL: I am now ready to resume the practice of my profession, after an absence of four years; during which time I have been connected with the Union Army.

*In the possession of the doctor's youngest daughter, Arna (Mrs. Broome), of Los Angeles, is the worn remnant of the counter brush used by her father in the old log drug store; she has stated (1943) that the brush would be available for a local museum of relics.

I do this, believing that the experiences I have thus added to my former knowledge, will render me none the less efficient. Residence one block above Dickson's mill."

It was in 1866 that Dr. Twitchell identified himself most actively with the promotion of medical science locally by joining with a small group of physicians in organizing the Fillmore County Medical Society, at a meeting held on October 17 in the office of Dr. Lafayette Redmon in Preston. Dr. Twitchell was the first president of the society and he held the presidency for several consecutive terms, during the important organizational period and through 1869, in which year the state legislature, on March 9, approved an act directed at the elevation of medical practice in the state. In this period of professional prominence Dr. Twitchell was known in the county as a public speaker of ability on medical subjects; notices of his lectures, which were given without charge, appeared from time to time in the newspapers. In 1871 he became a member of the Minnesota State Medical Society, which had been revived in 1869, and in 1879, co-operating with the State Board of Health, he was one of the eleven physicians of the county who supplied data for the official reports on the incidence of diphtheria. The chief of his earliest medical contemporaries in Chatfield was Nelson W. Allen, Isaac S. Cole, Luke Miller and Augustus H. Trow. In 1869 came H. Thomas and from the seventies on into the nineties there were many others, some of whom stayed a short time and some for many years. A few of them were John C. Dickson, Milton A. Trow, John C. Fate, Aaron M. Stephens, Florence J. Halloran and Charles McH. Cooper.

Although after the Civil War Dr. Twitchell resumed his medical practice and related activities, his health had been so depleted by his arduous military service that he no longer could carry on all of the strenuous duties of a country practitioner, and as time went on he became increasingly engaged in occupations other than medical. In the early eighties this physician entered seriously into civic affairs, especially in the legal department, serving various terms as village justice; the last time, in 1887, he was named thus in a special act of the legislature incorporating the City of Chatfield.

In 1885 Mrs. Twitchell, because of her failing health, moved from Chatfield to Santa Barbara, California, and her daughter Carpie soon followed to be her attendant and companion. Dr. Twitchell, who also was now almost an invalid, remained for a few years in the rambling old homestead with the daughter Arna and a little granddaughter, Anna Spencer Twitchell, whose mother had died, but in 1891 these three moved permanently from Chatfield to Hamilton, Ohio, the home of Dr. Herbert E. Twitchell. A year later Dr. Refine W. Twitchell joined his wife in California, and there he died on October 9, 1893; Martha Carpenter Twitchell passed away on June 17, 1896; both are buried in the beautiful cemetery on the outskirts of Santa Barbara, overlooking the ocean.

Of the five children of the family, it has been stated that Steven died in infancy. Sarah Edna, the eldest, a graduate of the University of Minnesota, an able teacher in the schools of Minnesota and South Dakota and a successful business woman, for a time proprietor of the Flandreau Roller Mills, died in Flandreau, South Dakota, on December 25, 1901. Carpie was married to William C. Hall; Mr. and Mrs. Hall lived at different times in Santa Barbara and Long Beach and, finally, in Los Angeles. Arna became Mrs. William J. Broome; Mr. and Mrs. Broome lived in the East until

1911, since when they have made their home in Los Angeles (1943). Herbert E. Twitchell, M.D., died at Dayton, Ohio, in 1929.

In Chatfield there are those yet living who recall Dr. Refine W. Twitchell as a man of kindly and strong personality, a physician wise in his day, gentle with his patients and in his family, intrepid in the line of duty and service, civic and professional.

John Darwin Utley, born in 1866, a graduate of Rush Medical College in 1890, was licensed on July 8, 1892, to practice medicine in Minnesota and soon afterward he filed his certificate in Fillmore County. In that summer Dr. and Mrs. Utley came from St. Croix County, Wisconsin, to Spring Valley and established their home in the village. Their only child, a daughter who died in infancy, was born in Spring Valley.

For the greater part of twenty-four years, as nearly as can be determined, Dr. Utley followed his profession in the community, building up an excellent medical and surgical practice and holding the confidence of his patients and associates. Well into 1916 he was active in the Southern Minnesota Medical Association, which he had joined early after its organization in July, 1892, and also in the Houston-Fillmore County Medical Society, which was formed in May, 1904, giving papers at the meetings and serving on committees. In July, 1916, the *Journal-Lancet* announced that Dr. J. D. Utley of Spring Valley had taken over the Midway General Hospital between Minneapolis and Saint Paul and would continue its work, and he presumably left Spring Valley early in that summer.

In December, 1918, *Minnesota Medicine* carried an item stating that Dr. Utley, of Saint Paul, recently had been appointed a captain in the Medical Reserve Corps and had gone to Camp Cutler, Battle Creek. In the early twenties Dr. Utley, by then a resident of Minneapolis, left Minnesota for California; Mrs. Utley had died not long after they had moved from Spring Valley. For his first year or two in California Dr. Utley practiced medicine in Ocean Park, for the next six years in Montrose, and since 1931 he has been in La Crescenta (1943).

G. H. Vance was in the village of Fillmore, in Fillmore Township, in the early eighties, judging from a single entry (1880-1881) in the *Minnesota State Gazetteer and Business Directory.* His name was not found in any other directory, general or medical, nor has other reference to him been observed.

(To be continued in the February issue.)

A. E. CARDLE, M.D.

President, Minnesota State Medical Association

President's Letter

The Minnesota State Medical Association enters a new year in its progress. We should look forward to the coming year as a time for service to all. Important problems lie ahead. While at times great difficulties may arise, I have no doubt that with such a splendid membership as is possessed by our Association, whatever problems face us will be solved with purpose and wisdom. The privilege and honor to serve this membership as president is deeply appreciated.

As Sixth District councilor, I learned the value of the great instrument which our State Association has become, an instrument through which every doctor in Minnesota has an extraordinary opportunity to exert influence for the public good. That may seem like a broad statement to make, but let us analyze it for a moment—let us examine this instrument which we doctors in this state have created. Every good physician, we realize, by merely doing his job is carving himself an enviable record of "good works." The primary aim of medicine is service to humanity, particularly the relief of suffering and, if possible, its prevention. A physician who dedicates his life to that high purpose has outlined for himself a difficult assignment, one which will take an entire lifetime to complete and, even then, will never be quite finished. By joining the State Association, a physician takes on more than just his professional responsibility. He has accepted a place in the ranks of a body called "organized medicine," through which he will undoubtedly derive much personal benefit, but to which he will also have to contribute in order that it may be maintained. Physicians working individually can perform a great many social services, it is true; but physicians banded together in the cause of common good can do even more. This is the team work which is so necessary to the future of medicine. Only by so doing can we maintain the type of medical life for which we have striven. What gains have been made by organized medicine in the past have come through the unselfish service of men who have had vision. It is this vision which I hope every member in our Association can grasp. We need it now and shall need it in the days to come. The forces that are working to destroy our "way of life" must be fully understood by every member. These are serious times and need serious thought.

During my membership in this Association of ours, I have watched it become more and more a service organization. For example, countless times I have seen various groups or agencies come before our Council or our House of Delegates seeking our advice and looking to us for leadership in matters of public concern. Further proof that ours is a service organization is shown in the increasing number of problems undertaken by our hard-working scientific and economic committees. Rural health, nurse shortage, disease control, extension of medical service and other perplexing problems are under intensive study at the present time. Through the combined efforts of every member of the Association, these problems can one day be solved. Not only is there determination to work together within our own ranks, but there is also increasing evidence of a desire to unite our efforts with those of the other professions which are a part of the health service picture. We are just beginning to realize the tremendous possibilities of a joint-attack by all of the allied health professions on the problems that beset us. This, then, is the instrument which we have created—an organization through which we can pool our resources so as to amass sufficient strength to overcome the obstacles lying between us and the goals to be achieved.

In anticipating what lies ahead in the coming months, I am grateful for the fine spirit of cooperation which has been so carefully developed and encouraged by my predecessors in office. The officers who will serve you in the coming year fully appreciate the honor which has been accorded them. They will serve you faithfully and well, as their predecessors have done. They wish to know all of the needs of the Association and its members. As one of these officers I look forward to the pleasure of becoming more intimately acquainted with the component medical societies and their members.

My best wishes to you all for a happy, successful and progressive year.

A. E. Cardle

Minnesota State Medical Association

NEW YEAR PROBLEMS

As we start the New Year, there is one outstanding need which towers over all others in its significance and that is the crying need for implementing the United Nations with an international force which will be effective in preventing war. All other needs—international or national—important as they are, are second in importance. If, in the setup of the United Nations, this cannot be accomplished, another organization which will provide an effective police power to prevent military aggression by any nation in the world, with membership open to all nations, seems to be the only answer. Another war involving the use of atom bombs, whose destructive power has been developed a hundredfold since the war, is unthinkable. Release, too, from the need of large military armaments would enable nations to devote their major energies towards reconstruction, for which there is such a woeful need today.

While we do not hesitate to express an opinion on the United Nations, the Marshall Plan is a controversial subject, involving continued shortages, continued high prices and high taxes in our country, and control of expenditures in foreign countries with eventual overproduction and probable repetition of the 1929 collapse.

On the home front there is the possibility that the Wagner-Murray-Dingell Bill will again be submitted for Congressional action. This, in our opinion, will be the most important decision Congress may be called upon to make. The fate of the bill will decide whether socialism in this country is to be extended to include medical practice or not.

Perhaps next in importance in our home economy is the need for a great reduction in the cost of our government. The innumerable bureaus in Washington and federal subsidies of states for activities which should be financed by the states themselves only serve to maintain taxes at rates which prove burdensome to all income groups and prevent financing of new industries. The government can do its part in breaking the vicious circle of high taxes, high wages, high costs of commodities, and high cost of government. Labor can do its part by going to work.

Our country with its vast resources and private initiative has always been able to meet both economic and political crises successfully. This has involved considerable muddling on occasion when economic laws have been interfered with. It is to be hoped that our law makers have come to realize that economic laws cannot be broken with impunity.

AMERICAN ACADEMY OF GENERAL PRACTICE

There has been a widespread feeling among general practitioners for some time that some steps should be taken to dignify their professional status. The great majority of M.D.'s are engaged in general practice, and they care for the majority of individuals who seek medical advice. While a section on General Practice in the American Medical Association was established at the San Francisco meeting in 1845, no nation-wide organization of general practitioners had made much progress until the American Academy of General Practice was founded June 10, 1947, by the officers and members of the Section on General Practice of the AMA on the occasion of the AMA meeting at Atlantic City. Although members of the new Academy must be members of the AMA., the organization is independent and distinct. The Academy, however, asserts its intention to support the AMA in every way.

The following quotation from the Constitution will clearly show the purposes for which the Academy was founded:

1. "To promote and maintain high standards of the general practice of medicine and surgery.
2. To encourage and assist young men and women in preparing, qualifying, and establishing themselves in general practice.
3. To protect the right of the General Practitioner to engage in medical and surgical procedures for which he is qualified by training and experience.

4. To assist in providing postgraduate study courses for General Practitioners, and to encourage and assist practicing physicians and surgeons in participating in such training.

5. To advance medical science and private and public health."

Qualifications for membership in the Academy include a state license to practice. Actual participation in general practice for at least three years, high moral and professional character, a year's rotating internship in an approved hospital or the equivalent in postgraduate training. That membership shall mean more than simply joining the organization, members will be required to devote at least 150 hours during every three-year period to postgraduate study—credit to be given for attendance at various medical meetings. Provision is made in the By-Laws for the establishment of state and county branches. An initiation fee of $10.00 and yearly dues of $15.00 are stipulated. An application for membership form may be obtained from Dr. Stanley R. Truman, Secretary, 1904 Franklin Street, Oakland 12, California.

The American Academy of General Practice is said to be growing rapidly in membership. The purpose of bettering general practice, for which the Academy was founded, is beyond reproach. If the Academy can stimulate the establishment of more postgraduate centers for general practitioners, with resulting greater attendance at county, state, sectional and national meetings, its existence will be justified. If not, it will have no *raison d'être* and will eventually fall into a state of innocuous desuetude.

MINNESOTA HEART ASSOCIATION PROGRAM

WITH diseases of the heart and circulation generally conceded to be the most important unsolved problem of medicine, it is intended that a major part of the program of the Minnesota Heart Association will be designed to provide supplemental educational aids for the medical profession.

It is intended that those aids should be provided through publications, pamphlets and the services of a Speakers Bureau, personnel of the Bureau to be available upon request of any county medical society for informal discussion of the problems of cardiovascular disease and emphasizing a progressive, objective approach toward reduction or possible elimination of those problems.

It is also intended in the program of the Minnesota Heart Association to stimulate research, both at the University of Minnesota and in smaller communities where facilities are available for clinical research along lines of clinical evaluation of advances in knowledge in cardiovascular disease.

To initiate and carry out the program of the Minnesota Heart Association, certain inevitable expenses are involved. They include costs of office space and equipment, clerical help, printed material, postage and other incidental charges, especially during the critical 1948 organizational period.

Meanwhile, the participation of Minnesota physicians as members of the Minnesota Heart Association can well mean the successful operation of the program. As members, physicians of Minnesota will also be adding their interest and voice to the development of the Association.

The eleven Minnesota physicians and five laymen who constitute the Board of Directors of the Minnesota Heart Association as it now exists (operating from the 20th Floor, Medical Arts Building, Minneapolis 2) are hopeful that other physicians in the state will promptly aid the program through their participation as members, since medical practitioners in general would stand to benefit by development of a program aimed at supplemental medical education in cardiovascular disease.

As Dr. L. A. Buie announced in his President's Letter in the October, 1947, issue of MINNESOTA MEDICINE, the Council of the Minnesota State Medical Association has approved the organization of the Minnesota Heart Association.

PAUL F. DWAN, M.D.
President, Minnesota Heart Association

GERMAN MEDICINE

AN account of what appears to be a very reliable investigation of medical research and training in Germany under the Nazi regime, including the war period, has appeared recently.* The question has arisen in our mind as to what, if any, valuable scientific facts were learned as a result of the sadistic experiments carried out on the thousands of helpless individuals in Germany under the Nazi regime in the name of science. This article answers the question.

It seems that the Technical Intelligence Di-

*Roueche, Berton, Zweckwissenschaft. The New Yorker, August 9, 1947

vision of the U. S. Department of Commerce sent a representative to Germany following the war to ascertain what developments in science, including medicine, the Germans had made during the war. They chose Hans Lowenbach, associate professor of neuropsychiatry at Duke University in Durham, North Carolina, as their investigator. He is a native of Dusseldorf, received his medical training in Germany, and was doing research in the Kaiser Wilhelm Institute in Berlin, when on June 3, 1934, Hitler's blood purge took place. Having some Jewish blood in his veins, he escaped after considerable difficulty to Norway, spent several months in Norway, and then served for three years as a ship doctor on a Norwegian whaler. With the help of friends at Johns Hopkins, he came to Baltimore in 1938 on the German quota from South Africa and obtained a job in research at Johns Hopkins. In 1940 he joined the faculty at Duke University.

Dr. Lowenbach made an exhaustive investigation of the scientific research which had been going on in Germany during the war. He reports that medical research during this period had been restricted by order to only those matters which might have a practical application—Zweckwissenschaft, so called. Research for research's sake was entirely abandoned. He lists eleven papers published during this period, all of which were of only passing interest. These included one in an artificial hand; a new method of steriling agar-agar; a survey suggesting that stocky individuals stand a hot, dry climate best; and analysis of structural abnormalities found in the brains of persons suffering from congenital mental disorders. Compared with the developments attained in our country during this period, such as penicillin, sulfadiazine, blood plasma, the Rh factor, et cetera, they seem insignificant. The results of the barbarous experiments on human beings have been absolutely nil and merely provided a sadistic delight to those who perpetrated the atrocities.

Dr. Lowenbach reports that the medical training under the Nazi regime has been of poor quality. All that is left of German medicine is a handful of old men. The younger men are provincial in their medical knowledge and complacent in their idea that the brilliant period in German medicine has not come to an end. His description of a brain operation performed in Munich at which he was a spectator, the diagnosis wrong and no provision being made in advance for a blood transfusion, suggests the type of surgery being practiced in Germany today.

To German scientists goes the credit of the first experimental work with sulfanilamide in December, 1932. It had first been synthesized in 1908. The first report of its clinical use was made by Domagk in an article in the Deutsche Medizinische Wochenschrift of February 15, 1935. This was before the Nazis took over in Germany. The development of the other sulfa drugs was accomplished outside of Germany, notably in England and America.

DIRTY LINEN AIRED

RECENTLY two articles appeared in *The Reader's Digest,* calling attention to certain reprehensible practices which are taking place in medical practice. None of those mentioned is new, and the profession has voiced its disapproval of such practices for years. How extensive they are and how many members of the profession are involved, we are unable to say.

The splitting of fees has always been frowned upon by the medical profession. Such a practice might well involve bidding for patients by the specialist, with higher fees charged by the specialist, and is bound to influence the referring physician in his choice of consultant. While the practice doubtless exists, we question whether it is widespread.

According to *The Reader's Digest,* the practice of rebating part of the cost of eyeglasses to the oculist by the optician is widespread, and the manufacture of lenses is in the nature of a monopoly. If so, the medical profession should take active steps to put an end to what amounts to fleecing the public by certain members of the profession.

As to the accusation that too many needless operations are performed, this cannot be denied. The figure of 9,000,000 a year is undoubtedly a gross exaggeration. There are many borderline cases where there is room for an honest difference of opinion. This applies particularly to the tonsil and appendix operations, which lead the list. It is the operations performed for revenue only that should be heartily condemned, and each hospital must be the guardian of the public by preventing such crooked procedure.

It is not pleasant to have our dirty linen aired. The way to prevent such criticisms is to keep our linen clean.

Miscellaneous

THE CLINICAL PATHOLOGIST VERSUS THE STATE HEALTH LABORATORY

During the annual session of the Minnesota State Medical Association, held at Duluth in July, 1947, the House of Delegates passed a resolution petitioning "the State Board of Health to include in its laboratory service Rh typing in order to make this service readily available to all practicing physicians."

This action was taken apparently without having given due consideration either to the fundamental merit of the proposition, or to the sentiments of the practicing clinical pathologists who hold membership in the Association.

The clinical pathologist objects to the resolution on the following grounds:

(1) The clinical pathologist, a fellow practitioner and member of the Association, who is materially affected by this resolution, had not been consulted before it was acted upon. The Rh determination is admittedly a laboratory procedure, and as such, it belongs in the sphere of the practice of clinical pathology.

(2) The Rh determination is not an emergency measure affecting public health, nor is it related to the control of communicable diseases. It can be carried out in the usual course of practice in any existing laboratory.

(3) The Rh determination by the state laboratory would invariably lead to blood grouping in general, as well as the Rh typing of male members of the population, since they are closely related in transfusion practice.

(4) The newly married or pregnant women may have their Rh determined at any time, not by the state laboratory as a public health or emergency measure, but by a private laboratory purely as a routine procedure.

(5) The technique of Rh determination is as simple as that of blood grouping and cross matching, since potent and reliable anti-Rh sera are now plentiful. The difficulty encountered in the past which probably prompted the resolution, was due mainly to the scarcity of reliable anti-Rh sera. This situation no longer exists, and all technicians who are trained to do blood grouping can perform the Rh test with equal skill and accuracy. The only caution suggested, here, would be that facilities for consultation should be made readily available in doubtful or important cases.

(6) The clinical pathologist claims that, since the Rh determination is within the sphere of his specialty, he may rightly expect a revenue from the performance of these tests for the practitioners. To deny him this right by the official action of his fellow practitioners would seem uncalled for, since there are a number of clinical laboratories throughout the state, directed or advised by a qualified clinical pathologist,† which are equipped to render not only the simple Rh determination but the more complicated serological procedures which may be required in the diagnosis and treatment of cases suffering from Rh incompatibility. It should be emphasized here that the clinical pathologist is fully cognizant of his obligations to the indigent and would gladly offer his services to him without cost whenever requested to do so.

Discussion

The clinical pathologist is a practitioner of medicine in the same sense as any of the members of other specialists. He is entitled to the support and protection of organized medicine. His future destiny may affect the destinies of all other members of the medical profession.

Unfortunately for the professional and economic security of the clinical pathologist, the diagnostic services of the state laboratory in infectious and communicable diseases in recent years has developed to such an extent that the medical profession looks to it more and more for aid in laboratory diagnosis, not only because of the excellent service it renders, but because of the elimination of the expense which it otherwise entails. The practice is now so universally appreciated, there is a tendency on the part of the practicing physicians not only to take full advantage of the present facilities of the state laboratory, but to advocate the extention of its services to include all diagnostic tests in order to "cushion" the cost of such services to the patient, ignoring completely the place which the clinical pathologist occupies in the practice of medicine. Coupled with this unfortunate trend is a more fundamental, yet less appreciated, fact that the field of clinical pathology and laboratory medicines, by its very nature, conveniently furnishes a fertile soil for the propagation of the seed of state controlled medicine, and that, combined with the public health aspects of the medical practice in general, the state laboratory may become the spearhead of socialized medicine, which may eventually affect not only the practice of clinical pathology, but that of radiology, pediatrics, obstetrics, or any other specialty.

This situation which threatens the very existence of the clinical pathologist as a medical specialist, and which, indeed, denies the principle of free private enterprise to a group of practitioners, is probably an important factor in the present scarcity of clinical pathologists. Young graduates are hesitant and cannot easily be persuaded to specialize in clinical pathology, since they realize full well the future of the specialty seems uncertain and uninviting.

This means that the smaller hospitals and communities will continue to be deprived of adequate clinical laboratory service except through the facilities of re-

This article was prepared at the suggestion of the Council, to enlighten the position the clinical pathologist takes on the diagnostic laboratory services rendered by the State Board of Health Laboratory, with special reference to the Rh determination. The opinions expressed, however, are the author's own.

†A list of practicing clinical pathologists in the state will be furnished upon request.

mote metropolitan laboratories, or through the services of the state laboratory.

In order to remedy this unsatisfactory situation, and to obtain adequate and on the spot laboratory service for rural hospitals and practitioners, and in order to uphold the principle of private enterprise for all, the clinical pathologist would propose to interest young medical graduates to enter into the specialty by assuring them of a productive field from which they may derive an attractive and satisfying practice, without the fear of "competition" from the state laboratory. To that end, he would suggest the establishment of a number of local community health centers in various parts of the state, each including a well-equipped hospital with adequate laboratory service under the direction of a trained clinical pathologist, who should be afforded an opportunity to personally serve local physicians and who, for economic reasons, may supervise several neighboring laboratories within the radius of 25 or 50 miles. This should give adequate, individualized laboratory service to all sections of the state. Moreover, he should be encouraged to avail himself of the facilities of the Department of Pathology of our Medical School for consultation, and to act as advisor and supervisor of an educational program for the local physicians whom he serves.

If this proposal were carried out, it should become unnecessary for the state laboratory to perform such diagnostic procedures as the Rh determination, tumor diagnosis, and the like, which certain public health officials and socially minded physicians are advocating, and might mean a definite deterrent to a threat of socialized medicine. It should stimulate initiative and incentive in the clinical pathologist, to fully equip his laboratory to render such diagnostic services as the state laboratory might otherwise render.

The clinical pathologist recognizes the leadership and the ability of the Minnesota State Board of Health Laboratory in research and diagnosis, by reason of the high qualifications of its scientific personnel and the economic advantages it enjoys. He looks upon it as a consultant and final authority in public health laboratory diagnosis. He recognizes the peculiarly desirable place it commands in promoting research and publicity relating to diseases which are of utmost public concern. He appreciates a healthy influence it exerts upon the practice of medicine in general and clinical pathology in particular. Such undertakings as the serologic evaluation program for participating laboratories currently being carried out, the statistical cancer survey service now being inaugurated, and other practical investigations dealing primarily with public health, are welcome contributions which the state laboratory can make without actually entering into the practice of medicine.

The clinical pathologist feels that where public health is not of immediate concern, clinical laboratory services should be left in his hands, and that he should not be placed in the role of a competitor in the practice of his specialty against the state operated laboratory. To burden the state laboratory with diagnostic tasks which primarily belong to the clinical pathologist might seem wise and expedient to some physicians, and a welcome sign to the advocates of socialized medicine. It would be accomplished, however, only at the sacrifice of a principle on which American medicine rests, and from which there should be no retreat.

KANO IKEDA, M.D.

MINNESOTA ACT RELATING TO LICENSED PRACTICAL NURSES

The law defines the practice of nursing by a licensed practical nurse as "the performing for compensation or personal profit, services required in the nursing care of the sick, not involving the specialized education, knowledge, and skill required in professional nursing." The law states in part: "It shall be a misdemeanor for any person to practice nursing as a licensed practical nurse in this state unless such person shall have first obtained a license from the Board, but this act shall not prohibit any person from nursing the sick for hire, who does not in any way assume or represent to be a 'licensed practical nurse.'"

The following is general information regarding the minimum qualifications for applicants for State Board examination and licensure as licensed practical nurses:

1. *Age.*—Applicant must be eighteen years of age or over.

2. *Character.*—Applicant must be of good moral character.

3. *Personal Fitness.*—Applicant must have a pleasing personality, give attention to own personal hygiene, show a sympathetic understanding of patients' problems, and have an appreciation of her own limitations, but possession of sufficient self-reliance to inspire confidence in the family.

4. *Health.*—Applicant must be in good physical and mental health.

5. *Education.*—Applicant must have completed at least an eighth grade education or its equivalent as determined by the State Department of Education.

6. *Practical Nurse training.*—Applicants might qualify for examination for licensure if they have had practical nurse training or the equivalent as indicated in one of the several groups below:

(1) Completion of and graduation from a program for the training of practical nurses which has been accredited by the Minnesota State Board of Examiners of Nurses; such a program to be not less than nine months in length.

Equivalents Effective for the Year 1948

(2) Completion of a systematized course of instruction and supervised experience in the care of the sick, of at least nine months' length; course not accredited by the Minnesota State Board of Examiners of Nurses; such a program to be evaluated by this board.

(3) Former student in an accredited school of basic

BARUCH PROPOSES PLAN FOR HEALTH INSURANCE

Speaking before a meeting in New York recently, Mr. Bernard M. Baruch, wartime economic stabilization director, presented his own theories about what this country needs in the way of health insurance. He proposed a health program to assist the medically indigent and hinted that government should be allowed its "legitimate part" in medicine.

Speaking before 600 doctors and hospital administrators at a dinner celebrating the progress of the Blue Cross plan in New York, Mr. Baruch detailed a program for improving medical and hospital services and advocated a form of health insurance for low income groups who are unable to pay for voluntary insurance such as the Blue Cross plan offers.

Mr. Baruch's proposals included the establishment of a new Cabinet post to handle health and human welfare problems. In his argument he cited American Medical Association estimates in 1939 that two-thirds of the nation's population could not afford the cost of serious illness.

Condemns Medical "Rear Guard Action"

Too long, Mr. Baruch declared, doctors have been "fighting a rear guard action." He was expressing dissatisfaction with the medical profession's program to provide adequate medical care. Several eastern newspapers played up Mr. Baruch's remarks and some of them suggested that the medical profession needs further stimulation in its efforts to avoid socialization. Mr. Baruch (who is the son of a physician) implied that the voluntary medical service plans now operating are too costly for the low income groups. For them he boldly endorsed some form of compulsory health insurance, financed through payroll deductions, with some government aid and with the patient retaining the right to choose his own doctor.

On the surface, Mr. Baruch's plan may appear harmless, but a second glance reveals the possibility of serious consequences. The payroll deductions would be very small, true, but they would be supplemented by employer and government so as to total a figure much higher than that which medical costs ever would reach under the voluntary system. The high cost of administering the program would absorb a greater share of the funds collected and only a relatively small amount would remain to pay for medical services rendered.

Then, too, it is known that payroll deductions will mean even less take-home pay than ever for the lower income groups. That will surely stimulate organized labor to demand further wage increases and will up production costs and the price of goods to the consumer. Thus begins a vicious circle which will widen continually until costs are all out of proportion to the original deductions taken out for the prepay program.

The Voluntary Way Is Cheaper

Figures bear out the contention of the medical profession that the voluntary method of enrolling subscribers in plans for budgeting the cost of medical and hospital care is much cheaper than compulsory government-administered plans.

The sincere effort that organized medicine has made to promote and extend prepayment medical care plans can be cited as positive proof that medicine is not on the defensive, nor is it "fighting a rear-guard action."

To those who complain that the rising cost of medical care is putting good health out of reach of the majority of our people, medicine has this to say: Medical care is expensive and is becoming more expensive; yet, in comparison to the national income, it is a shrinking item.

An analysis of the cost of medical care has been made by the American Medical Association Bureau of Medical Economic Research, which

presents facts and figures to prove that statement. It further points out that patients nowadays are getting far more for their money in terms of longer life than they ever got before.

Trend Is Toward Compulsion

Mr. Baruch's proposals are only one example of the tendency of many of today's deep thinkers to arrive at the conclusion that compulsion is the answer to our social problems. Mr. Baruch explains that "all law imposes compulsion." With that as a base line he then cites government's part in education and housing and suggests that government should also handle medicine in a like manner. With all of that he still maintains that he is opposed to socialization since "it leads ultimately to the police state, degradation of the individual and lessened well being." Right there Mr. Baruch has refuted his own argument, but medicine has an even better, more concrete answer.

In reality, just because people are compelled to set aside so much for medical emergencies, it doesn't necessarily follow that they will be in any better position to do so. If two per cent of a worker's income will supply him with complete hospital and medical service for himself and his family, and he is unable to give up such a small amount out of each pay check voluntarily—will he be more able to pay under a compulsory system?

Those unable to pay their own hospital and medical bills are today able to secure services free. Physicians generally supply care where it is needed and charge moderately when the patient has modest means—and not at all when the patient is in financial straits.

"What of the Little Fellow?"

Mr. Baruch insists that none of the prepay plans so far advanced—other than the so-called "compulsory health insurance"—provide for the low-income group. Some can afford voluntary health insurance, Mr. Baruch says; but, he asks, "What of the little fellow?" Mr. Baruch might well consider that that "little fellow" (who makes up about two-thirds of our population) affords the government a tremendous source of revenue. Furthermore, persons who live within their means, as all people should, will be able to provide ordinary medical care for themselves.

Mr. Baruch proposes to protect the little fellow with a strong, centralized, paternalistic government health program. Does he not realize that health programs are best administered locally as dictated by the needs of the individual community? Can he not foresee the possibility of such a system working ill to that very man he is proposing to help—the little fellow?

EXPERIMENT IN GOVERNMENT CONTROL OF MEDICINE FAILS

A couple of months ago, when an order came to cut down on services to subscribers in order to stretch a shrinking budget, San Francisco doctors gave up trying to support the Health Service System of that city, which had been in operation about ten years.

The doctors began resigning *en masse,* refusing to deviate from good medical practice. Said the physicians (both members of the San Francisco Medical Society and nonmembers alike): "We can take cuts in our fees, but we won't cut the quality of medical care!"

The Health Service System of San Francisco was created by the voters in 1937. The plan made it compulsory for the city's 12,000 employes to enroll in the plan; their dependents could elect to participate, or not, as they desired. Payroll deductions covered the premiums, and average monthly payments were around $3.40.

Plan Financially Unbalanced

The plan's financial base was extremely shaky and countless times the San Francisco County Medical Society warned of impending disaster and suggested reforms. In fact, the plan lost $37,578 last year despite its earned income of $529,330. In an attempt to regain its bearings, the Health Service System increased its premium rate 25 per cent. That had to be done even though physicians were only being paid 85 cents on a dollar.

The final attempt to keep the plan going was the plea to participating physicians from the medical director of the Health Service System: "Reduce your services!"

Physicians can surely make diagnoses without so many laboratory tests and x-rays, the medical director of the plan declared in his statement to the doctors. He reported that the results of several hundred examinations, particularly reports from x-ray laboratories, had been surveyed and

the conclusion had been drawn that from 50 to 60 per cent of these tests were unnecessary.

The medical society answered by pointing out the folly of taking chances on improper diagnoses just to cut operating costs. It further showed that x-ray and clinical tests amounted to a total of $33,944 during the year—hardly enough to account for a deficit of more than $37,000.

Thus has ended another "shining example" of government medicine.

AMA INTERIM SESSION AIMED AT GENERAL PRACTITIONER

The annual interim session of the American Medical Association in Cleveland, January 5 to 8, promises to provide unusual opportunities for postgraduate education and for discussing problems which beset the general practitioner.

Meetings to be held include the AMA House of Delegates, the Council on Industrial Health, the National Conference for County Medical Society officers and a special Midwest Regional Conference of the Council on Medical Service.

The AMA delegates meet the first two days, January 5 and 6 to transact Association business. At the same time Industrial physicians and others concerned with industrial health will convene for their Eighth Annual Congress. General practitioners supply a large part of the medical services which workers receive through industry and they are being invited to attend the sessions. The program has been constructed with the general practitioner in mind and will include discussions of first aid in emergency services in industry, physical examinations, administrative practices, applied physiology, aviation medicine, radiation medicine and practical expositions of occupational disease management, traumatic surgery and rehabilitation.

"Grass-Roots" Conference Meets

A second of the highly successful "Grass-Roots" Conferences of County Medical Society officers will be held on Tuesday evening, January 6. It will be devoted primarily to the problems of general practitioners—how to create more of them, how to uphold their prestige and their role as leaders in the community.

The AMA scientific program, to be presented beginning Wednesday morning and continuing two days, will be devoted to subjects of current interest and again slanted toward the doctors in general medicine. Each session is to be supplemented by panel discussions where doctors will have full opportunity to present individual questions they may have.

Four speakers on the program are from Minnesota: E. H. Rynearson and Albert Snell, Rochester, and C. D. Creevy and L. G. Rigler, Minneapolis.

On Wednesday the newly created AMA gold medal award to the outstanding general practitioner of the country will be presented. The AMA reports that hundreds of nominations have been received from state medical associations and various community and civic organizations. Biographies of the three top candidates selected by the executive committee of the Section on General Practice and the Board of Trustees will be submitted to the House of Delegates, which will choose the recipient on Monday morning.

Midwest Regional Conference

On Sunday, January 4, the day prior to the opening of the AMA interim session, the Council on Medical Service will hold a Regional Conference, with representatives from the six states of Illinois, Indiana, Kentucky, Michigan, Ohio and West Virginia. The AMA has announced that these regional conferences have been highly successful and is planning to hold them from time to time.

Another AMA-sponsored conference is coming up in February which is being watched with interest because of the vital problem with which it deals. This year marks the third of the series which is coming to be an annual event. This conference is the Conference on Rural Health to be held February 6 and 7 in Chicago.

Farmers and doctors are establishing by means of this conference a working liaison and the exchange of ideas and opinions at these conferences show promise of accomplishing a great deal in the rural health problem in the near future.

COUNTY OFFICERS MEETING

Officers of the component medical societies of the Minnesota State Medical Association will convene for their annual meeting at Hotel Lowry in Saint Paul on Saturday, February 28. Among the important topics to be considered will be an up-to-date progress report on the Minnesota Hospital Survey and Construction program, in which physicians in the state are vitally interested.

Saint Paul Woman Pleads Guilty to Forging Narcotic Prescriptions

Re United States of America vs. Frances C. Zink

On November 7, 1947, Frances C. Zink, forty years of age, who gave her address as the Lowry Hotel, Saint Paul, Minnesota, entered a plea of guilty in the United States District Court in Saint Paul, before the Honorable Robert C. Bell, to an information containing two counts of violations of the Federal Narcotic laws. Judge Bell suspended the imposition of sentence and placed the defendant on probation for five years on condition that she remain in the custody of the United States Marshal and be taken to the United States Public Health Service Hospital at Lexington, Kentucky, for treatment for drug addiction.

The defendant was arrested on October 18, 1947, by Saint Paul police officers after she attempted to have a forged narcotic prescription filled at a Saint Paul drug store. The druggist became suspicious because the defendant had sent a seventeen-year-old girl with the prescription. The investigation disclosed that the defendant had stolen prescription blanks from at least three Saint Paul physicians, and according to the Federal Bureau of Narcotics, had forged approximately twenty prescriptions calling for a total of 322 tablets of dilaudid in a period from September 8 to September 19, 1947.

The defendant, at the time of her arrest, was a buyer for the women's apparel department of a Saint Paul department store. Prior to coming to Saint Paul in June, 1947, the defendant had operated a dress shop at Madison, Wisconsin, for several years.

Saint Paul Woman Convicted of Shipping Misbranded Drugs in Interstate Commerce

Re United States of America vs. Carry Grace Colwell also known as Mrs. J. H. Colwell, trading as the Colwell Radium Company

On December 16, 1947, Mrs. Carry Grace Colwell, sixty-six years of age, 257 Johnson Parkway, Saint Paul, Minnesota, was sentenced by Judge Dennis F. Donovan of the United States District Court in Saint Paul, to pay fines totaling $500, following her conviction by a jury on December 1, 1947, of shipping misbranded drugs in interstate commerce.

An information was filed against Mrs. Colwell on July 23, 1947, charging her with four violations of the Federal Food, Drug and Cosmetic Act, and particularly with those sections forbidding the shipment of drugs in interstate commerce that are misbranded or mislabeled. At the trial the Government proved that the defendant shipped radium ore to a patient in Ohio. The representations that accommpanied the shipment stated that the product was efficacious in the treatment of such diseases as cancer, tumors, poliomyelitis, Bright's disease, liver disorders, heart trouble, gall-bladder trouble, diabetes, tuberculosis, locomotor ataxia, syphilis and other ailments of human beings. Another product, radium penetrating healing balm, shipped by the defendant to a patient in Montana, was represented as being efficacious in the treatment of similar diseases. The jury refused to believe the representations made by the defendant and promptly found her guilty.

The defendant, prior to her prosecution by the United States authorities, was warned by the Minnesota State Board of Medical Examiners to discontinue her activities. Mrs. Colwell holds no license to practice any form of healing under the laws of the State of Minnesota. Unless she ceases her activities, a request will be made by the Minnesota State Board of Medical Examiners that the matter be given the attention of the state authorities.

MINNESOTA ACT RELATING TO LICENSED PRACTICAL NURSES

(Continued from Page 82)

professional nursing, although not a graduate of such a school, and having had theory and clinical experience during that time; such theory and experience to be evaluated by this board; plus at least one year's experience as a practical nurse.

(4) At least two years' experience in the care of the sick, which might include experience in hospitals registered by the American Medical Association under the direct supervision of registered nurses or licensed physicians who have given personal instruction to the applicant; or in homes under the direction of licensed physicians or under the direction of public health nursing agencies.

(5) Completion of a prescribed course in the armed forces such as: U. S. Army, medical or surgical technician; U. S. Navy, Coast Guard, or Maritime Service, as hospital apprentice or pharmacist mate; plus one year's hospital experience in the armed forces.

In sections (3) and (4) above, unless some of such experience shall have been within the five years' period immediately preceding application, such applicant may be requested to obtain a "refresher" course or more recent experience before application will be accepted. Also in sections (3) and (4) above, such experience shall have been varied in nature to qualify as equivalent to completion of a program in an accredited school of practical nursing.

When request for application blank for examination is made, please indicate under which section above you qualify. Further information and/or application blanks for examination may be obtained from the Minnesota State Board of Examiners of Nurses, 222 Minnesota Building, Saint Paul 1, Minnesota. Credentials submitted in application will be reviewed and verifications obtained by this Board.

BOWEL OBSTRUCTION

(Continued from Page 57)

evaluation, experiences and background in judging them.

In these deaths which I have reviewed, most of them were due to peritonitis. There were twenty-five cases of peritonitis (61 per cent). There were five patients who died of cardiac disease. There were three cases which were difficult to evaluate but in which death was apparently due to metastatic carcinoma. There were two deaths which were attributable to shock. One patient was a diabetic, and death was attributed to that. There were two deaths due to peritonitis and pneumonia and three due to pneumonia.

Minnesota Academy of Medicine

Meeting of May 14, 1947

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, May 14, 1947. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the President, Dr. E. M. Hammes.

There were fifty members and four guests present.

Minutes of the April meeting were read and approved.

The scientific program followed.

THE SURGICAL ASPECTS OF JAUNDICE

WILLIAM H. RUCKER, M.D., F.A.C.S.
Minneapolis, Minnesota

Jaundice is frequently the symptom of a condition that can only be relieved by surgery. Its treatment is definitely medical or surgical, contingent upon its basic pathology. Though its etiology is often complex and diagnosis at times extremely difficult, precise differentiation is essential if the patient is to be relieved and not injured by injudicious therapy or operative procedure.

The importance of jaundice to the surgeon is stressed by such reports as those of Snell[12] and Meyer[9] who both found approximately 60 per cent of all icteric patients amenable to surgery. That inaccurate diagnosis and incorrect treatment may be dangerous is attested to by White[21] who states that operations in cases of deep jaundice due to hepatitis or acute yellow atrophy have a mortality rate approaching 100 per cent and in cirrhosis of the liver 35 per cent. We know that ill-advised cholecystectomies may be harmful to undiagnosed congenital hemolytic jaundice patients, some 60 per cent of whom have gallstones. It is also evident that unoperated prolonged biliary obstruction leads to permanent liver damage and cirrhosis.

The surgeon will certainly make fewer inaccurate diagnoses and obtain better results, if he has a clear understanding of jaundice, its etiology, and the important methods of its differentiation. This is only possible through a knowledge of the anatomy and functions of the liver and other organs and tissues involved in its production.

The liver consists of cords of polygonal cells enclosing the bile canuliculi and surrounded by Disse's lymph spaces. The sinusoids in contact with these spaces contain the reticulo-endothelial or Kupffer's cells. The liver has a unique vascular system, in that it has two afferent blood supplies, the portal vein and the hepatic artery, and but one efferent, the hepatic veins. The hepatic artery joins with the portal vein to supply the sinusoids, thus allowing a mixture of arterial blood with the venous blood from the spleen, stomach and intestines. The sinusoids empty radially into a central vein which joins with other central veins to form the hepatic vein which empties into the vena cava. The polygonal and Kupffer cells perform the many bio-chemical processes of the liver and are intimately involved in the production of jaundice.

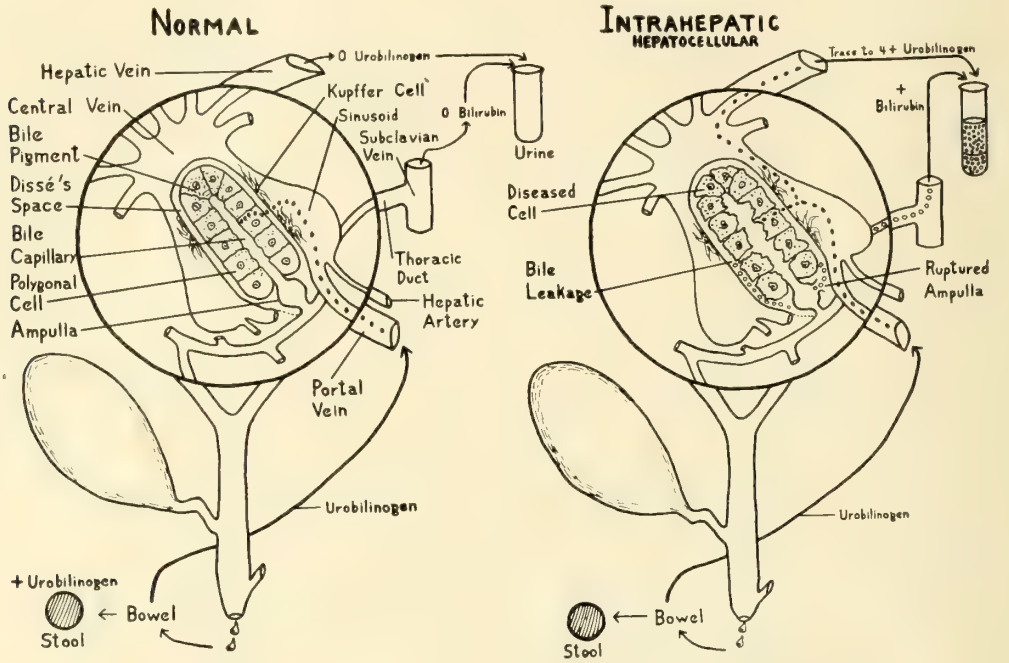
C. *Combined Hemolytic-Obstructive*



Jaundice is due to an excess of the bile pigment, bilirubin, in the blood stream. Bilirubin is formed from hemoglobin in the destruction of red blood cells by the reticulo-endothelial cells, particularly those of the liver, spleen and bone marrow. Normally this pigment passes from the Kupffer cells through the polygonal cells, where it probably loses its globin radical,[16] into the bile channels. In the bile it passes through the common duct into the duodenum to be changed, later in the colon, by anaërobic bacteria, to urobilinogen. About one-half of this urobilinogen is picked up by the portal system and returned to the liver where all but a trace again passes into the bile. In order to have an excess of bilirubin in the blood stream, some intra or extra hepatic disturbance must interfere with this normal chain of events.

If the liver cells become diseased and normal passage of pigment from sinusoid to bile capillary does not occur, the resultant jaundice is known as hepatocellular. When the bile ducts became obstructed and the bile is backed up, the hyperbilirubinemia that results is recognized as obstructive jaundice. In the event a hemolytic agent causes such a great destruction of red corpuscles that the liver cells are unable to pass all the bilirubin into the bile channels, and the excess is left in the blood stream, we have what is termed hemolytic jaundice. Frequently, combinations occur and are identified as mixed jaundice. In both the hepatogenous and the obstructive types, bile escapes into the lymph and blood streams; hence, they are also described as regurgitation jaundice. In the hemolytic form this does not occur, and it is classified as a retention jaundice.

While these classifications are important in understanding the pathogenosis of jaundice, the surgeon will be primarily interested in whether the patient's icterus arises from a condition within or without the liver. His services will usually be of little value if the disease is confined to the liver. Therefore, some such classification as the following will be more suitable to him.

Intrahepatic or hepatogenous jaundice may be due to diseased liver cells, obstruction of bile capillaries, or combinations of both. It may be caused by infections, poisons, and various diseases, or it may result from either primary or metastatic malignancy. In the former it may be mild, and the patient recover in a few weeks or months, or severe, and result in acute atrophy or cirrhosis. There will usually be a history of infection or exposure to a hepatoxin, no pain, an orange tinged icterus, an enlarged liver, clay-colored stools and a highly colored urine. In the advanced cases pigmentation of the skin, ascites and edema, spider naevi, pallor and mental disturbances may be present. Early in hepatitis the urine contains large amounts of urobilinogen. After jaundice appears this often drops to a small amount, to arise again as recovery takes place. Bilirubin is usually present.

The surgeon should keep in mind homologous serum jaundice because it closely simulates extrahepatic ob-

structive jaundice and may develop some sixty to ninety days following the injection of serum or plasma. Schiff[11] reports a case where plasma was used following the removal of a common duct stone and jaundice developed some two months later. Careful study established the diagnosis of serum jaundice and a hazardous operation for stricture or overlooked stone was avoided.

Metastatic carcinoma of the liver is probably twenty times as common as primary hepatic malignancy. Its source is usually the intestinal tract, the genitourinary organs, the breast or the lung, though it may arise from almost any tissue of the body. In both conditions weakness, loss of weight, anemia, pain, fever, edema, and ascites are common symptoms. Palpable tumors will be evident in the liver and the spleen is often enlarged. Enlarged nodes in the supraclavicular space, rectal shelf, or inguinal regions, masses in the intestinal tract or other evidences of malignancy may point to metastasis in the liver.

Operation will play the leading role in extrahepatic jaundice. It may be either obstructive, from a blockage of the large bile ducts, or hemolytic, from excessive hemolysis of the red blood cells. In the obstructive type bile may be transiently, intermittently, or persistently blocked. Cholecystitis is the common cause of transient jaundice but occasionally pancreatitis or duodenal ulcer may be the instigator. Spasm of the common duct or sphincter of Oddi may rarely cause a mild transient jaundice. Intermittent obstructive jaundice is usually caused by a common-duct stone, though at times a benign or malignant polypoid tumor of the duct, papilla of Vater, or duodenum has been found to be the source. Persistent exclusion of bile is usually indicative of malignancy or stricture. However, benign ductal or extraductal tumors may very occasionally prove the cause.

Carcinoma may attack the common or hepatic ducts or they may be secondarily invaded from malignancy in the pancreas, liver, gall bladder, or duodenum. Congenital atresia of the bile ducts may occur and demand operation, yet one is more frequently confronted with those strictures that occur post-operatively due to trauma or section of the common duct. Inflammation may be the cause of a benign fibrous tumor of the duct or eroding gall-bladder stones may be the source of a granuloma which causes complete obstruction of the choledochus.

Transient jaundice is rarely important or difficult to diagnose. In the intermittent type a previous history of gall-bladder stones, when considered with the relative rarity of the occurrence of polypoid tumors, will usually point to choledocholithiasis. Persistent exclusion of bile is most often encountered with either malignancy or stricture, and only very occasionally with benign

Fig. 2. Extrahepatic jaundice.

tumors. Congenital stricture should raise no problem and the history of previous operation should point to the diagnosis in the acquired type. In the great majority of cases of extrahepatic obstructive jaundice, then, differential diagnosis must be made between intermittent and complete blockage; stone on the one hand and malignancy on the other.

In the intermittent type certain rather definite findings are evident. Usually one is confronted with a middle-aged woman having a history of previous attacks of gallstone colic, stones perhaps confirmed by x-ray, her present illness being initiated by chills, fever, and colic followed by jaundice, clay-colored stools, and bile-tinged urine. Because of the intermittency of the blockage, the color of the urine and the stool, as well as certain laboratory tests, will vary. Urobilinogen will appear in the urine and stools in varying quantities from day to day, depending upon the degree of obstruction. Bilirubin will be present in the urine because bile is regurgitated into the lymph and blood streams. The liver will usually be tender and enlarged, and the gall bladder not palpable, but sclerotic and containing stones. The jaundice will often have a greenish tint and pruritus will frequently be present.

The complete obstruction of malignancy will usually occur in older males and loss of weight and weakness will be marked symptoms. Other findings will be compatible with the persistent blockage of bile; jaundice of a deep hue, pruritus, consistently acholic stools and a markedly dark urine. There will be an absence of urobiliogen in the stool and urine as no bile will reach the intestinal tract. Regurgitation of bile, however, will cause the urine to show a positive reaction for bilirubin. Pain will depend upon the location of the lesion. If the malignancy is primary in the ducts, chills, fever and colic will be evident. This is also true if the gall bladder is the primary site. When the head of the pancreas is involved, usually a dull, persistent, boring pain will be present in the right epigastrium. However, if the primary site is in the body of the pancreas, pain will be referred to the lower dorsal and lumbar regions. A dull aching pain in the right hypochondrium is complained of in carcinoma of the liver. Epigastric distress, nausea and vomiting will be symptoms in malignancy of the stomach or duodenum. On physical examination there will be a deep greenish jaundice, probably evidence of scratching and petechiae, and usually an enlarged liver and distended gall bladder. Masses and nodes may be palpable.

Hemolytic jaundice probably results, as Rich[10] states, not only from an overhemolysis of red blood cells and resultant excess of bilirubin, but also through inefficient anemic liver cells being unable to perform their normal functions. In the acute form the hemolytic agent may be an animal, vegetable, or drug poison, bacterial toxin, protozoal parasite, mismatched transfusion or other miscellaneous known or unknown hemolytic substances. In the chronic form such diseases as sickle cell anemia, Mediterranean anemia, congenital and acquired hemolytic jaundice, et cetera, occur. Also, it may be present with such chronic disorders as carcinomatosis, Hodgkin's disease, pernicious anemia and leukemia. Hemolytic jaundice is of interest to the surgeon not only because it may occur in extensive burns, mismatched transfusions and chronic and malignant diseases but principally because he can bring relief by splenectomy to those patients with congenital and acquired hemolytic jaundice.

Congenital hemolytic jaundice is hereditary and follows Mendel's law. The most generally accepted theory is that the offending hemolysin is developed in the spleen. It is a type of jaundice characterized by splenomegaly and a typical blood picture of microcytosis, spherocytosis, reticulocytosis and increased fragility of the red blood cells. The disease has active and inactive stages. The symptoms are those of anemia, i.e., weakness, dizziness, et cetera. The jaundice is a typical lemon to golden yellow and there is no pruritus. The family history, the appearance and symptoms of the patient and especially the specific blood picture and the indirect Van den Bergh reaction should make certain the diagnosis. It should seldom be confused with other forms of jaundice.

In chronic hemolytic jaundice there is such a great concentration of bile that in the majority of cases pigment stones are formed. These stones may occur in the gall bladder or bile ducts and at times cause obstruction and therefore a combined hemolytic-obstructive jaundice.

Intrahepatic and all forms of acute and chronic hemolytic jaundice, with the exception of the congenital and acquired forms, should be treated by the internist and carefully avoided by the surgeon. In the operator's field will lie the extrahepatic obstructive type and these two spherocytic anemias. As we have stated, little trouble should be encountered in diagnosing the anemias. The problem lies in differentiating the hepatogenous from the obstructive, particularly in the late cases. Obstruction of bile in time results in liver cell damage, and, conversely, prolonged hepatic cell disease causes obstruction of the bile canuliculi. Hence, as time passes, the condition approaches one of mixed jaundice, and the primary etiology towards which treatment must be pointed is lost in the complexity of the situation. This fact stresses the importance of early study and the necessity of a thorough history and physical examination and discounts the value of late liver function tests.

Steigman, Popper and Meyer[14] reported that they were able to diagnose correctly 62 per cent of all icteric patients with a complete history, a careful physical examination and one urinalysis for bilirubin and urobilinogen, and increased this percentage to 79 per cent by plotting curves of the daily estimations of these two urinary tests. The liver function tests were helpful in 16 per cent, and 5 per cent were undiagnosable.

Though it is true that meticulous clinical evaluation of the icteric patient is the most important single factor in diagnosis, the surgeon must have a knowledge not only of the simpler essential laboratory procedures and also the better established liver function tests, but also of other available diagnostic methods. He will then be able to corroborate his clinical findings, receive assistance in differentiation, follow the progress of the disease, and evaluate the condition of the liver so that

the patient may be properly prepared for operation.

Of the extremely large number of tests, many are too complicated for the average hospital laboratory and some are indefinite and confusing. An attempt is therefore made in the following group to list only those tests and procedures that are clear, essential, and not too complicated.

Diagnostic Procedures

1. Complete Blood
2. Van den Bergh—quantitative
3. Urine Tests
   - (a) routine
   - (b) urobilinogen
   - (c) bilirubin
4. Stools—urobilinogen
5. Liver Function Tests
   - (a) Cephalin-Cholesterol Flocculation
   - (b) Thymol Turbidity
   - (c) Alkaline phosphatase

9. Liver Biopsy.

A complete blood test, besides detecting evidence of anemia, infection, et cetera, may lead to the diagnosis of congenital hemolytic jaundice, leukemia, pernicious anemia, and other diseases.

The quantitative Van den Bergh procedure will not only give the amount of direct and indirect reacting bilirubin and differentiate regurgitation from retention jaundice, but also the total serum bilirubin. Repetition of the test will indicate the fluctuation of jaundice, thereby helping in differentiation and in determining the progress of the disease.

Routine urinalysis will determine the health of the kidney, which is of particular importance in liver damage and in the accuracy of liver function tests. The urobilinogen and bilirubin tests are simple and extremely helpful as the sketches have shown. They give much information in regard to the condition of the liver cell and bile capillary.

Examining the stool for urobilinogen tells one whether bile is entering the intestine.

Watson[15] states, "The thymol turbidity test is more uniformly negative in jaundice due to extrahepatic biliary obstruction, while the Hanger or cephalin cholesterol flocculation test is more likely to be positive in cases of parenchymal liver disease, especially cirrhosis. The thymol turbidity test is the simplest, quickest, and most reliable test, technically. If negative, however, it should be followed by the Hanger test."

Alkaline phosphatase is usually higher than 10 Bodasky units in obstructive, and less than 10 units in hepatocellular. Cholesterol is usually increased in obstructive and diminished in liver cell disease. The prothrombin test is particularly valuable to the surgeon. Prothrombin is manufactured by the liver cells. Its production is frequently decreased in both obstructive and hepatogenous jaundice and bleeding tendencies may therefore become evident. If vitamin K is given to the obstructive case, the prolonged prothrombin time will be decreased, while no relief will be obtained in the hepatic patient. This is called the prothrombin response test.

At the University of Minnesota, Watson[15] uses a chart upon which he plots the many liver function tests and thereby obtains a better over-all picture of liver function.

Examination of the duodenal contents may prove of value. Cholesterol crystals and pus will point to gallstones. Blood may indicate malignancy. Blockage at the Ampulla of Vater will diminish both bile and pancreatic enzymes, while obstruction of the common duct will interfere with the flow of bile but allow normal amounts of enzymes.

While the ordinary Graham-Cole x-ray of the gall bladder will usually be of little assistance, films of the gastrointestinal tract may show deformities or shadows of neoplasms responsible for blockage of the ducts.

Before operation is attempted in the difficult diagnostic case, peritoneoscopy and liver biopsy should be considered. In competent experienced hands these procedures have given much information and proved valuable in differentiating extrahepatic from intrahepatic jaundice.

In spite of the many methods of diagnosis now available, there will remain a number of cases in which diagnosis will be impossible. However, this percentage should remain small, if the clinician understands and uses intelligently the procedures now available to him. Perhaps the future will bring an x-ray technique capable of distinguishing these two forms of jaundice.

Summary

1. The surgical import of jaundice is stressed by the fact that more icteric patients are amenable to surgery than to medical therapy.

2. Whether treatment shall be medical or surgical is dependent upon accurate diagnosis, and an incorrect choice may prove harmful or even disastrous.

3. An understanding of the pathogenosis of jaundice is essential in differentiation.

4. A classification of jaundice is made from the viewpoint of the surgeon and some salient symptoms and findings of each type are discussed.

5. Though careful clinical study and simple laboratory procedures will diagnose the majority of icteric patients, nevertheless liver function tests and other procedures are necessary in the diagnosis of some 20 per cent.

6. It is evident that simpler, less confusing, and improved methods must be developed to differentiate intrahepatic from extrahepatic jaundice before all these patients can be properly diagnosed and correctly treated.

Discussion

Dr. E. M. Jones, Saint Paul: I have enjoyed Dr. Rucker's paper very much. He has presented a subject that is of equal interest to the surgeon and the internist. The surgeon is called upon to treat individuals with extrahepatic obstruction, and the largest percentage of these obstructions are due to gallstones. As Dr. Rucker has pointed out, it is sometimes very difficult to state whether the obstruction is due to gallstones or a malignant process. I feel that, if it is at all possible, in cases with a diagnosis of malignancy causing the obstruction, an exploration should be carried out. Some years ago, I had occasion to review a large series of cases of disease of the gall bladder and the extra-biliary ducts at the Ancker Hospital. In this group two cases were found that had been diagnosed as having jaundice due to a malignant process. At autopsy the jaundice was found to be due to gallstones. Shortly afterwards another case presented a similar picture, and the same diagnosis was made. At exploration, a stone was found obstructing the common duct. The stone was removed, and the patient made a good recovery. If one such case is found in many hundreds of explorations, the exploration is well worth while. Sir Berkeley Moynihan once said that the most important person at an operation is the patient. That we are all cognizant of this is borne out by the great stress placed on preoperative care. There is no group of cases that requires more exact, painstaking preoperative care than the jaundiced patient. The results have been much better since this practice has been carried out.

Dr. Otto W. Yoerg, Minneapolis: Dr. Rucker has given us a very comprehensive résumé of jaundice. I know he has given much of his time to evaluating the essentials of so large a subject.

Dr. Rucker stressed the fact that diagnosis should be made early because as jaundice progresses laboratory findings become more inaccurate.

Early operation in surgical jaundice, as Dr. Rucker stated, is important as it is well known that delay in operation leads to liver damage which is often irreparable and which may account for incomplete relief from symptoms after operation.

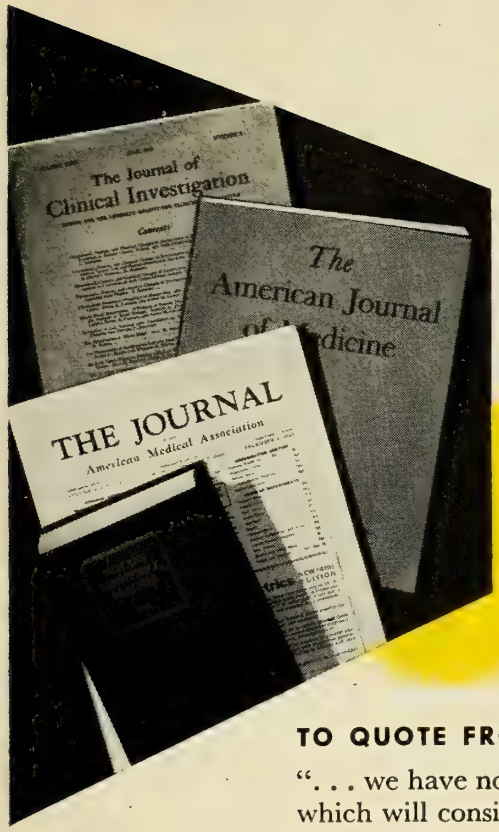
Hemolytic jaundice is not common and is easily overlooked. A young man of thirty-four recently came under my care complaining of weakness and of being tired. He was moderately jaundiced, but was unaware of this except that he had known that he had always been of a rather yellow color. He stated that he had consulted a number of physicians, all of whom had told him that he had gallstones and suggested their removal. Examination of the abdomen was negative and the spleen was not palpable. X-rays disclosed a large gallstone. A complete blood examination made at one of our better hospitals disclosed a hemoglobin of 40 per cent and findings of a secondary anemia. He was given parenteral liver and kept under observation for three or four weeks without change in his jaundice. A tentative diagnosis of a possible hemolytic jaundice was made and he was referred to an internist for further study which confirmed the diagnosis. I removed a 2000-gram spleen followed by the disappearance of his jaundice and a full recovery. It is of interest that blood studies of the mother, three sisters and one brother disclosed fragility of the red cells, but all were symptom free. Gallstones are present, as Dr. Rucker stated, in 50 to 60 per cent of hemolytic types of jaundice. Enlarged spleens are not always palpable and it might be well to ray the left as well as the right upper abdomen which should disclose any enlargement of the spleen if present. Accurate blood studies are, of course, essential and should be done by a well-trained careful laboratory technician.

I have enjoyed hearing Dr. Rucker's thesis which he has so ably presented.

Dr. Rucker, in closing: I want to thank Drs. Jones and Yoerg for their kind remarks. And I wish to thank the Academy for the privilege of becoming a member.

AN ENLARGING CONCEPT OF THE PORPHYRINS IN CLINICAL MEDICINE

Inaugural Thesis



CECIL J. WATSON, M.D.
Minneapolis, Minnesota

Abstract

This study will include a brief discussion of the nature of the porphyrins of clinical and physiological significance: namely, protoporphyrin, the two coproporhyrin-isomers, and the uroporphyrins. The earlier confusion with hematoporphyrin and the means of distinction will be discussed. Reference will be made to simple quantitative methods for protoporphyrin, the total urinary coproporphyrin, as well as uroporphyrin and its precursor, porphobilinogen. Reference will also be made to a relatively simply method of analysis of the percentage of the coproporphyrin isomer A, which is applicable to as little as 100 c.c. of urine. This method of determining isomer distribution, depending upon differential precipitation in 30 per cent acetone in the cold, has permitted a study of coproporphyrin isomer excretion in various diseases which was not hitherto possible, because of the previous necessity of isolation of the crystalline esters from large volumes of urine, often as many as thirty or forty liters, with subsequent determination of the melting point of the crystals.

A discussion will then follow of the total coproporphyrin excretion in the 24-hour urine and the isomer distribution in various diseases under normal and pathological conditions, including: (1) hepatitis and

Increasing recommendation for **gold therapy** in active rheumatoid arthritis

TO QUOTE FROM RECENT AUTHORITATIVE SOURCES:

". . . we have not found any therapy other than gold therapy which will consistently and in a high percentage of cases change the course of the disease."[1]

"Gold therapy at present seems to be the only drug which shows promise of checking the activity of rheumatoid arthritis; . . . ."[2]

REDUCED TOXICITY

"The high incidence of reactions attributable to the formerly employed larger doses . . . has been largely obviated by the use of more conservative doses."[3] Moreover, "therapeutic results are quite as good with smaller doses. . . ."[4]

DECHOLIN HYDROCHOLERESIS Encourages Biliary Tract Drainage

● **Percentage Increase in Composition and Quantity of Bile Flow**

Ivy, A. C., et al: Am. J. Dig. Dis. 7:333 (Aug.) 1940.

HYDROCHOLERESIS—

an increased production of thin liver bile—is a desirable approach to therapy of non-obstructive biliary tract disturbances.

DECHOLIN—

by producing an increased flow of bile—washes stagnant, infected bile from the intrahepatic and extrahepatic biliary passages, removing pus-laden material and discouraging the ascent of infection.

HOW SUPPLIED:

Decholin in 3¾ *gr. tablets. Packages of* 25, 100, 500 *and* 1000.

Decholin

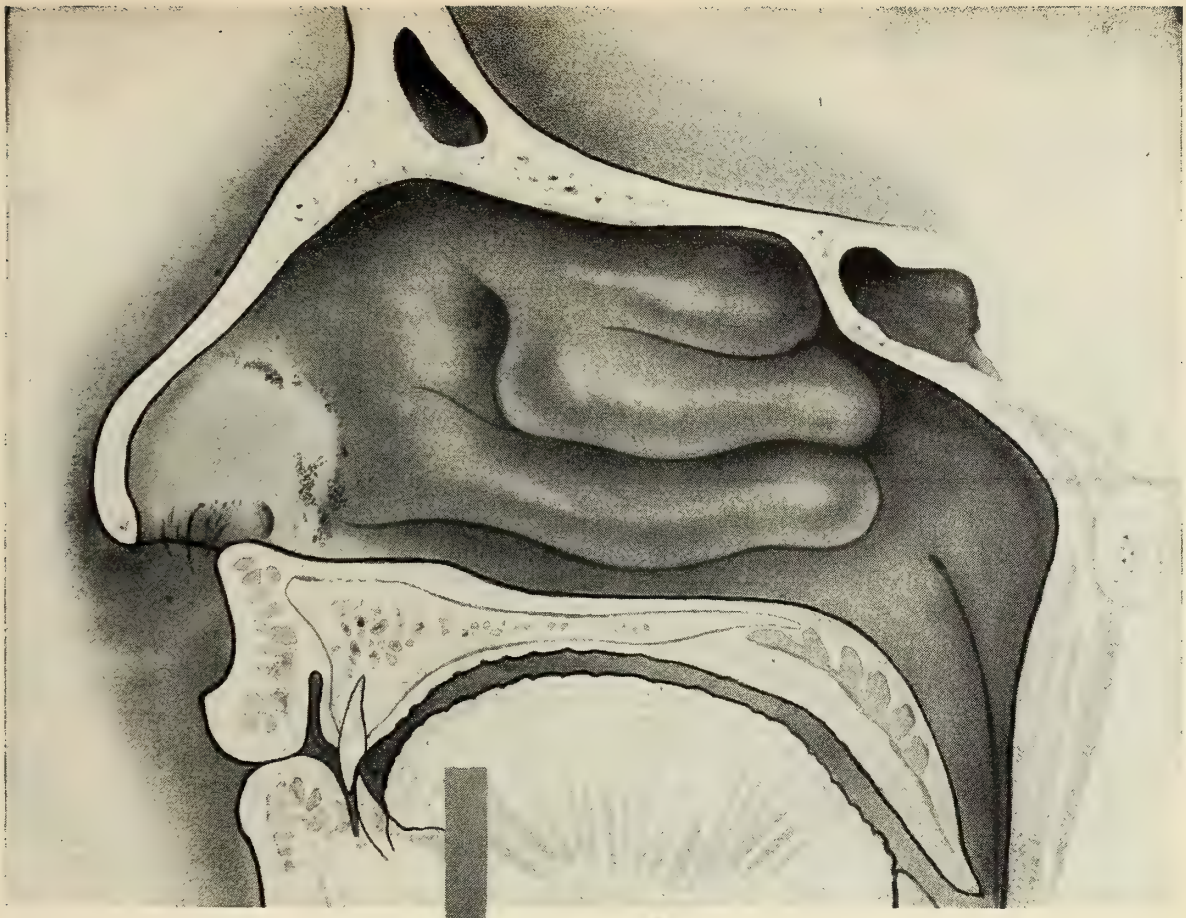
cirrhosis; (2) alcoholism; (3) anemias and blood dyscrasias; (4) affections of the nervous system with particular reference to poliomyelitis and other neurotropic virus diseases; and (5) idiopathic coproporphyrinuria with abdominal pain.

It will be emphasized that porphyria in which uroporphyrin is formed and excreted is an independent disease in which there is an inborn error of metabolism. Porphyria is thus to be sharply differentiated from the symptomatic coproporphyrinurias of various types as alluded to above. Two main forms of porphyria will be discussed briefly; namely, the intermittent acute form, and the congenital or light-sensitive form. While the latter is undoubtedly very rare, the former occurs much more frequently than has been realized. Its confusion with various other disease states will be mentioned. The clinical and laboratory manifestations in porphyria will be alluded to.

Discussion

DR. E. L. ALTHAUSEN, University of California Hospital, San Francisco (by invitation): I certainly cannot add anything constructive to this presentation. However, I was also very much interested in hearing this paper and can say that a very valuable field of investigation has been opened and a great deal of work has gone into the presentation given here tonight. I shall inquire into the possibility of starting something similar when I get home.



DR. E. SHORR, Cornell University, New York City (by invitation): I am very much in Dr. Althausen's position of not having had direct experience with porphyrin metabolism. I came to Minneapolis with the idea of interesting people in various types of liver diseases and shall return to New York with greater interest in proporphyrins. I leave Minneapolis with regret. Like Dr. Althausen, I shall attempt to learn Dr. Watson's technique and feel sure it is going to add zest to our liver problem studies.

DR. S. E. SWEITZER, Minneapolis: Dr. Watson mentioned insecticides. Did he find any sensitivity to the use of DDT powder in delousing? We use it quite a lot at the Minneapolis General Hospital, and so far have not seen any cases of sensitivity.

DR. WATSON, in closing: I am very grateful to those who were so kind as to discuss my contribution. In regard to insecticides, I don't know what to say about DDT but I have no evidence that it causes anemia. I think insecticide injury is a matter of sensitivity. I remember very well a case as remarkable as any I have ever seen. A young man from North Dakota first came to the University Hospital in 1928. He was found to have aplastic anemia. The history states that he had been working in a grocery store with insecticide powders. He was transfused a number of times and allowed to go home. He went back to North Dakota where for two or three years he did not return to his former kind of work. Then he did return to it, handling insecticide powders again, after which he had a very severe relapse of his aplastic anemia. We followed him for six years, giving many transfusions. He died of a gas bacillus sepsis. Perhaps if he had avoided the insecticide powder, he might have been able to recover completely.

The meeting adjourned.

A. E. CARDLE, M.D., *Secretary*

ciliary

ACTIVITY IN COLDS

Ciliary motion carries away exudative debris in the upper respiratory passages. This action should not be inhibited by therapy of the common cold.

The isotonic solutions of Neo-Synephrine hydrochloride permit ciliary function to continue in an efficient manner, while congestion is reduced by vasoconstriction.

In Memoriam

JOHN FREDOLPH ALDEN

Dr. John Alden was born in Sweden on January 8, 1888. The names of his parents are not known. He left Sweden at the age of fifteen, came to the United States and settled in southern Minnesota where he went to school.

After finishing high school, he attended Gustavus Adolphus College in St. Peter and later attended Loyola University in Chicago. In 1916 he graduated from the medical department of Marquette University, Milwaukee, Wisconsin. His internship was served at St. Joseph's Hospital, Saint Paul, in 1916 and 1917, and he entered general practice in 1917.

In 1921 Dr. Alden married Zena Furberg. They had three children—Dr. John Fredolph, Jr., Virginia May and Robert William.

He was a member of the Alpha Kappa Kappa Medical Fraternity, the Saint Paul Athletic Club and the Automobile Club.

Dr. Alden was active in the Osman Temple, the Inter-Professional Men's Institute, the Ramsey County Medical Society, and the American College of Physicians and Surgeons. He was a staff member of Bethesda, St. Joseph's and Children's Hospitals.

On August 10, 1947, at Lake Owasso, while swimming from the shore to a sail boat moored near by, death came by drowning.

Dr. Alden represented a fine type of general practitioner which is becoming altogether too rare. He will be missed by his many friends both in and out of the profession.

He was a member of Gloria Dei Lutheran Church. Interment was at Acacia Park Cemetery.

GEORGE ALFRED MORLEY

Dr. G. A. Morley of Crookston passed away November 19, 1947, following a heart attack. He was seventy-nine years of age.

Dr. Morley was born March 15, 1868, in Juneau County, Wisconsin. He received his M.D. degree at Rush Medical College in 1897. He specialized in eye, ear, nose and throat diseases, which he had practiced for many years.

Dr. Morley was a former president of the Crookston public school system. He was a member of the Red River Valley Medical Society, the Minnesota State and American Medical Associations.

PETER ERNEST KIERLAND

Dr. P. E. Kierland, a practitioner of Alexandria, Minnesota, for the past four years, died in Chicago on November 29, 1947, en route to Florida.

Dr. Kierland was born at Rushford, Minnesota, May 18, 1878. He attended the University of Minnesota graduating from Rush Medical College in 1902. He practiced at Aberdeen, Washington, from 1902 to 1904, at Mahnomen, Minnesota, from 1904 to 1912, at Harmony, Minnesota, from 1912 to 1922, and at Alexandria from 1922 until his death.

He was a member of the Park Region District and County Medical Society, the Minnesota State and American Medical Associations.

Dr. Kierland married Elsie M. Ochsner of Henning, Minnesota, July 21, 1905. He is survived by his widow and three children, Dr. Robert Kierland of Rochester, and two daughters.

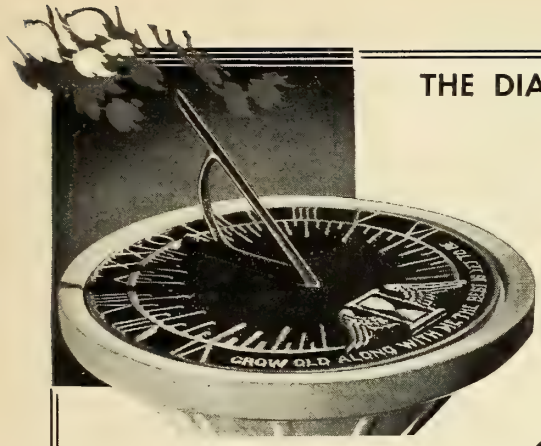
SAMUEL ROBINSON

Dr. Samuel Robinson died on September 17, 1947, at Santa Barbara, California.

Samuel Robinson was born February 23, 1877, at Augusta, Maine. He received the degree of B.A. in 1898 and of M.D. in 1902 from Harvard University; was an intern at the Massachusetts General Hospital, Boston, from 1901 to 1903. From 1903 to 1912 he practiced at Boston and from 1912 to 1915 at Clifton Springs, New York.

He entered the Mayo Clinic, Rochester, Minnesota, as head of the Section on Thoracic Surgery in January, 1915. He was first assistant in general surgery from 1915 to 1916; also, he was assistant professor of surgery, The Mayo Foundation, from 1915 to 1917. He left the Mayo Clinic, October 26, 1917.

During World War I, Dr. Robinson was chief of the surgical service, with the rank of major, at the Letterman General Hospital, Presidio, San Francisco. In 1918 he went to Santa Barbara to practice surgery. He was chief of the surgical staff of the Santa Barbara General Hospital and was a member of the surgical staff of the Santa Barbara Cottage Hospital and of the St. Francis Hospital.



Dr. Robinson was a fellow of the American College of Surgeons and a member of the American Medical Association, the American Association for Thoracic Surgery, the Interurban Surgical Society and the Pacific Coast Surgical Association.

JOSEPH MOSES

Dr. Joseph Moses, a prominent physician of Northfield, Minnesota, died November 18, 1947, at the age of sixty.

Dr. Moses was born November 17, 1887, at Herman, Minnesota. His family came to Northfield in 1894. After attending Carleton College, he attended the University of Minnesota Medical School where he graduated in 1914. After serving an internship at Minneapolis

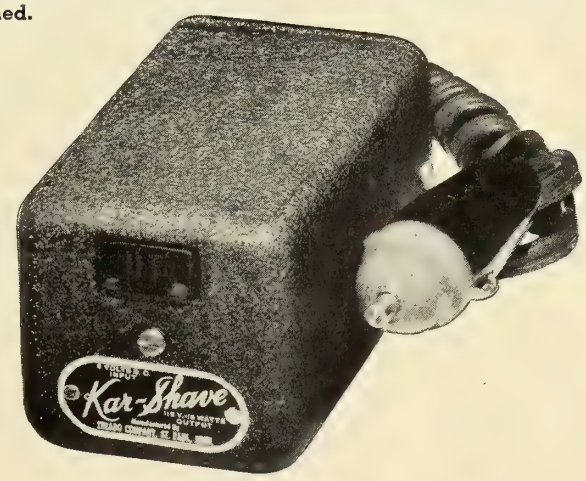
THE DIAGNOSIS IS CORRECT—

Kar-Shave saves Time

ONE hour today, thirty minutes tomorrow, time and time again for months and years, Kar-Shave can save segments of valuable time.

Physicians and Surgeons are finding the use of Kar-Shave to be the only means by which they can be clean-shaved on every call and occasion, day and night—without sacrificing valuable time for this routine but necessary detail.



On the way to a patient, a dinner, or a meeting, drive up to and park at the curb. Plug Kar-Shave into the cigar lighter connection on the dash of your car. Plug your electric razor into Kar-Shave. In a few moments the job is done. Smooth, clean.

Kar-Shave converts 6 volts D.C. to 110 volts at 15 watts. Only 2"x2"x3½" in size. Neat and permanent finish. Carried in glove compartment. Makes any electric razor work better. Built to last a lifetime. Ideal for lake cottage use also. Kar-Shave is fully guaranteed against defects in material and workmanship. Dealerships being established.

(Continued from Page 96)

General Hospital, he practiced at Adams, Minnesota, and then enlisted as a lieutenant in the Army Medical Corps, being stationed at Fort Riley, and Camp Pike, Arkansas. Upon his discharge with the rank of Captain, he located at Northfield becoming associated with the late Dr. Warren Wilson.

Dr. Moses was a member of the Rice County Medical Society of which he was one time president, the Minnesota State and American Medical Associations. He was also chairman of the Rice County Public Health Association and during World War II served as medical examiner for war services. He was a charter member of the Northfield Lions Club, serving as president, of the Masonic Blue lodge, the Odd Fellows, the Workmen and the American Legion. Other activities included participation in the organization of the Community Chest, membership on the Board of Education, and serving as vice president of the Northfield National Bank.

A lifelong Democrat, Dr. Moses served for several years as a member of the Democratic State Central Committee and, in 1936, was one of the Minnesota delegates who went to Philadelphia to renominate President Roosevelt for his second term.

On June 8, 1915, Dr. Moses married Edith Elizabeth Street of Northfield, who with a brother, Roy, of Northfield, three nephews and a niece survive him.

JOHN STEVENS

Dr. John Stevens, a practitioner at Gonvick, Minnesota, for thirty-five years, died at his home, December 1, 1947, at the age of seventy-two.

Dr. Stevens was born at Rockland, Maine, November 26, 1876. He graduated from the University of Minnesota Medical School in 1897, and practiced at Belfast, Maine, from 1898 until 1911. Returning to Minnesota in 1911, he located temporarily at Bagley, but in 1912 moved to Gonvick. In 1921, he took postgraduate work at the Postgraduate Hospital in Chicago.

Dr. Stevens served as village health officer and for a number of years headed the Board of Education of Gonvick. During World War I, he served as a medical officer with the 88th Division overseas.

Dr. Stevens married Bessie Marden in the East before coming to Minnesota. He lost her in the influenza epidemic of 1918-19. Later he married Mabel Newman. He is survived by his widow and a son, John, Jr., and also by a son by his former marriage.

He was a member of the Red River Valley Medical Society, the Minnesota State and American Medical Associations.

Friendship hath the skill and observation of the best physician, the diligence and vigilance of the best nurse, and the tenderness and patience of the best mother.—CLARENDON.

Bringing the Mountain to Mohammed

Through timely contemplation, you will find that the dearest and most valued possessions are those near at hand, and often overlooked while gazing at the horizon for the Utopia.

We have brought to your door the opportunity for a valuable possession.

It is sage advice, Doctor, to suggest that you apply for the noncancellable Accident and Health policy that has been made available to you by your Association.

The horizon holds no greater value.

Reports and Announcements

ARMY ORGANIZED RESERVE

A meeting of the 110th General Hospital of the Army Organized Reserve was held January 20, 1948, at 8:00 p. m. at Fort Snelling, Minnesota. Speaker of the evening was Lt. Col. Stanford Johnson, Director of Medical Administration, Branch 8 Veterans Administration, Minneapolis. Colonel Johnson gave a résumé of the conference which he attended December 15-19, 1947, at 5th Army headquarters in Chicago.

POSTGRADUATE COURSE IN DISEASES OF THE CHEST

The American College of Chest Physicians, Pennsylvania Chapter, and the Laennec Society of Philadelphia are sponsoring a postgraduate course in diseases of the chest to be held during the week of March 15-20, 1948, at the Warwick Hotel, Philadelphia, Pennsylvania.

The emphasis in this course will be placed on the newer developments in all aspects of diagnosis and treatment of diseases of the chest.

The course will be limited to thirty physicians. Tuition fee is $50 for members, and $90 for non-members.

Further information may be secured at the office of the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

NATIONAL CONFERENCE ON MEDICAL SERVICE

Chicago again plays host to the National Conference on Medical Service on February 8. Because the program features wide-open discussions of important controversial problems affecting medical practice, hospitals and nursing, the Conference promises to be of outstanding interest to general practitioner and specialist alike, according to Dr. F. F. Sladek, Traverse City, Michigan, secretary of the Conference.

President of the Conference, Dr. Creighton Barker, New Haven, Connecticut, will open the 1948 session in the Red Lacquer Room of the Palmer House at 9:30 a. m. The morning program will develop two viewpoints on the subject "The Practice of Medicine by Hospitals, Health Departments and Medical Schools" through papers presented by Everett W. Jones, general manager of the Modern Hospital, Chicago, and Dr. Lowell S. Goin, of Los Angeles. Dr. L. Fernald Foster, Bay City, Michigan, will speak on the subject, "Medical Public Relations Begin in the Doctor's Office." "Nursing Problems in America" will be reviewed by Dr. Thomas P. Murdock, of Meriden, Connecticut, and Janet Geister of Chicago.

The afternoon has been given over to panel presentations on the subjects, "General Practice and "Specialty Boards," participated in by Dr. Wingate M. Johnson, Winston-Salem, North Carolina; Dr. C. F. Wilkinson, Ann Arbor, Michigan; Dr. Leroy E. Parkins, Boston; Dr. Paul Titus, Pittsburgh, and Dr. C. N. H. Long, New Haven, Connecticut. This will be followed by discussion with general audience participation.

MISSISSIPPI VALLEY MEDICAL SOCIETY

The thirteenth annual meeting of the Mississippi Valley Medical Society will be held at Springfield, Illinois, on September 29 and 30 and October 1, 1948, under the presidency of Dr. W. O. Thompson, professor of medicine at the University of Illinois. The society now has a membership of nearly 1,000.

MIDWEST RADIOLOGIC CONFERENCE

The 1948 Midwest Radiologic Conference will be held at the Hotel Schroeder, Milwaukee, February 6 and 7, and will be followed by the annual conference of teachers of radiology in Chicago on February 8. Principal speaker at a dinner to be held on the evening of February 6 will be Dr. Robert R. Newell, professor of radiology, Stanford University School of Medicine, San Francisco.

Inquiries concerning details of the meeting may be sent to Dr. A. Melamed, Secretary, Milwaukee Roentgen Ray Society, 425 East Wisconsin Avenue, Milwaukee 2, Wisconsin.

NICOLLET-LE SUEUR COUNTIES SOCIETY

At the annual meeting of the Nicollet-LeSueur Counties Medical Society in St. Peter on December 3, Dr. L. E. Sjostrom, St. Peter, was elected president to succeed Dr. Hobart Johnson, North Mankato.

Other officers elected at the meeting were Dr. Martin Henry, St. Peter, vice president, and Dr. Alfred Sherman, St. Peter, secretary-treasurer. Dr. E. G. Olman-

Now More Than Ever The Physician's Advice Is Needed

Much confusion has resulted in the public's mind because of the conditions prevailing in the food field. Lessened food availability, the need of many people to economize, and the desire to cooperate with the government's aim toward world-relief, may well lead to deterioration of the nutritional state, unless competent guidance is offered.

The physician's advice appears particularly important in the realm of protein nutrition. Lack of appreciation by some people for the more economical cuts and grades of meat, as well as the variety (or organ) meats, frequently interferes with the use of these excellent sources of high quality protein.

All meat, whatever the kind or grade, or organ meat, supplies the essential amino acids indispensable for body maintenance, growth, repair and many other essential functions.

Furthermore, all meat—regardless of cut or kind—is 96 to 98 per cent digestible.

By encouraging wider utilization of lower priced meats the medical profession can render a real service to budget conscious patients in maintaining the quality of protein nutrition and the wholesomeness of the daily diet.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

son, St. Peter, was named as delegate to the state association meeting, with Dr. C. S. Strathern, St. Peter, as alternate.

GOODHUE COUNTY SOCIETY

Election of officers for the coming year was held at the annual dinner meeting of the Goodhue County Medical Society in Red Wing on December 4.

Dr. M. B. Flom, Cannon Falls, was named president of the society, while Dr. W. M. Akins, Red Wing, became vice president, and Dr. J. F. Brusegard, Red Wing, secretary-treasurer. Dr. R. F. Hedin, Red Wing, was named delegate to the state association meeting, with Dr. H. T. McGuigan, Red Wing, as alternate.

RAMSEY COUNTY SOCIETY

Newly elected officers of the Ramsey County Medical Society are Dr. J. R. Aurelius, president-elect; Dr. J. N. Gehlen, vice president, and Dr. Laurence D. Hilger, secretary-treasurer.

New president of the society is Dr. C. K. Williams, who was named president-elect one year ago and who succeeds Dr. John M. Culligan, retiring president.

ST. LOUIS COUNTY SOCIETY

Iron Range and Duluth practitioners gathered on December 11 at the Northland Country Club for the annual meeting and banquet of the St. Louis County Medical Society.

Principal speaker at the meeting was Harry C. Applequist, Duluth attorney, who delivered an address entitled "Lethargy in Our Social Order."

With election of officers, Dr. P. S. Rudie, Duluth, former president-elect, became president of the society, succeeding Dr. D. W. Wheeler, Duluth. Other officers elected at the meeting were Dr. Mark Tibbetts, Duluth, president-elect; Dr. J. P. Grahek, Ely, vice president, and Dr. Karl E. Johnson, Duluth, secretary.

SOUTHWESTERN MINNESOTA MEDICAL ASSOCIATION

In spite of adverse weather, more than fifty persons attended a meeting of the Southwestern Medical Association in Worthington on November 17.

Association members joined with auxiliary members for an evening smorgasbord dinner. After dinner, the two groups separated to conduct their respective programs. Association members heard Dr. John Moe, Minneapolis, speak on "Back Pain," illustrating his talk with motion pictures and slides. Members of the auxiliary heard an address on public relations by Mrs. Harold Wahlquist, national auxiliary public relations chairman.

The First Microscope...

For Both Medicine and Dentistry, the playful hobby of a Dutch spectacle-maker was of incomparable importance. "Spectacle-maker," *indeed!* What more weird "spectacle" than a tiny flea, lumbering huge, hairy and horrible through the lenses of Hans Janssen, about 1590?

Four men, each born between 1628 and 1637, were quick to grasp vital implications in Janssen's gadget, *independently but simultaneously!* With microscopes of their own make, Malpighi found the capillaries; Swammerdam found the red blood cells; van Leeuwenhoek found spermatozoa; and Hooke, whose microscope was the first to resemble today's, anticipated Schleiden's cell theory by 200 years.

But a doctor's legal liability was growing as fast as his knowledge. Sir Edward Coke, "father of the common law," ruled in 1615 that a doctor could be sued not only by a patient's employer for breach of contract, but also by the employee for malpractice.

Formerly of California, Dr. Walter H. Sutherland purchased the building and practice of Dr. C. L. Scofield, Benson, and began practice in Benson on December 1. After graduating from the College of Medical Evangelists, Los Angeles, California, in 1944, Dr. Sutherland served in the army until April, 1947.

* * *

In November, Dr. J. K. Butler of Carlton announced the opening of offices in Cloquet for the practice of Medicine and surgery. The offices are in the Trico Building at 12th and Cloquet Avenue, with office hours from 9:00 a.m. to 5:00 p.m. weekdays and 9:00 a.m. to 12:00 noon on Saturdays.

* * *

Formerly of Spring Grove, Dr. Orville M. Rotnem has moved to Mabel and opened offices for the practice of medicine. A graduate of the University of Minnesota Medical School, Dr. Rotnem practiced at Spring Grove after his release from the armed forces in May, 1947.

* * *

On behalf of the national Fraternal Order of Eagles, the Rochester chapter on November 18 presented Dr. Charles W. Mayo with a bronze plaque for distinguished service to the nation, "in recognition of contributions to the welfare of our country and active participation in civic affairs." Dr. Mayo is the fourth person to be so honored by the fraternal organization.

* * *

Principal speaker at the first annual meeting of the Faribault County Public Health Nursing Service, held in Blue Earth on November 20, was Dr. Robert N. Barr, chief of the section of administration in the Minnesota Department of Health. The meeting was held in conjunction with a meeting of the Blue Earth Parent-Teachers Association.

* * *

In recognition of his work in directing the Steele County x-ray survey, the Trudeau Medical Society at a meeting in November elected Dr. J. F. Shaefer, Owatonna, to membership in the group. In addition to directing the county-wide x-ray survey, Dr. Shaefer has been a member of the board of the Cannon Falls tuberculosis state sanatorium since 1946.

* * *

"Does Allergy Interfere with the Child's Development?" was the topic discussed by Dr. Albert V. Stoesser at a meeting of Section I of the Child Psychology Study Circle in Minneapolis on December 1. Dr. Stoesser is clinical professor of pediatrics at the University of Minnesota Medical School and director of the allergy clinics at the University and at Minneapolis General Hospital.

* * *

A senior physician at the Fergus Falls State Hospital since June, 1941, Dr. Werner Hemstead has resigned his position and has moved to Minneapolis to live with his son.

Fifty-five years of medical practice in Minnesota lie behind Dr. Hemstead, including twenty years as physician at the St. Cloud reformatory.

FOURTH ANNUAL CLINICAL CONFERENCE *of the* CHICAGO MEDICAL SOCIETY

Palmer House, Chicago, Illinois
March 2, 3, 4, 5, 1948

If you have attended one of these Conferences you probably are planning to come again in 1948. If you have not yet attended one, you should make plans now to be present.

These four days are packed full of many interesting features:

Subjects covering many fields of medicine are presented by outstanding speakers from all sections of the country.
Scientific exhibits on many topics presented attractively.
Technical exhibits unusually well presented on all the new drugs and equipment.
Panel discussions to arouse your interest.

Plan now to attend and make your own reservation at the Palmer House, Chicago so that you will not be disappointed!

At the start of the New Year, Dr. David Feigel, formerly of the Branton Clinic in Willmar, moved to Graceville and joined the staff of the Dr. I. L. Oliver Clinic. He replaced Dr. Gordon Vaughn, who, after practicing at the Oliver Clinic for four months, left for Minneapolis on December 20 to take postgraduate work at Minneapolis General Hospital.

* * *

The Chicago Medical Society has commenced publication of a weekly bulletin, *This Week in Chicago Medicine,* for the information of physicians who visit Chicago. Copies will be widely distributed throughout the country, are available at certain Chicago hotels, and may be obtained from the headquarters of the Chicago Medical Society, 30 North Michigan Avenue, Chicago.

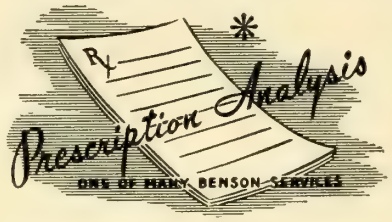
* * *

Plans and possible projects of the newly organized Mower County Health Council, first of its kind in the state, were described by Dr. Paul C. Leck, Austin, when he spoke to the Lions Club in Austin on December 8. Dr. Leck, as chairman of the Rural Medicine Committee of the Minnesota State Medical Association, is in charge of the county health council project in Minnesota.

* * *

On December 9, a group of physicians from China, Japan, Brazil, Hawaii, Central America and Mexico—most of them taking postgraduate work in public health at the University of Minnesota—visited Lafayette School in Saint Paul to observe the school's nutrition clinic. Under the auspices of the Christmas Seal organization, the clinic discovers nutritional needs of children and then provides hot lunches to meet those needs.

* * *



"Emotional Disturbances during Childhood and Their Effect on Adult Maladjustments" was the title of an address presented by Dr. Gordon R. Kamman, Saint Paul, at the annual meeting of the McLeod County Public Health Association in Glencoe on October 28. In Chicago on November 18, Dr. Kamman spoke on "The Value of the Rorschach" at a meeting of the Illinois Association for Applied Psychology.

* * *

Named outstanding practitioner of Goodhue County, Dr. M. R. Williams of Cannon Falls was the candidate of the Goodhue County Medical Society for the honor of being selected outstanding practitioner in Minnesota. Dr. Williams was given the county award in recognition of his work during the past several years, especially during the war years when he carried on as the only physician in Cannon Falls.

* * *

The King Haakon VII liberty medal has been presented to Dr. Ivar Sivertsen, Minneapolis, for services rendered to Norway's cause during World War II. Presentation of the medal was made at a banquet at the Minneapolis Athletic Club on December 12, 1947.

Dr. Sivertsen examined all members of the Norwegian Air Corps who passed through Minneapolis during the war on the way to Camp Little Norway, Canada. Ten years ago Dr. Sivertsen was presented with the Cross of St. Olaf by the Norwegian government.

* * *

Zumbrota acquired a new physician in December when Dr. C. S. Youngstrom, formerly of La Crosse, Wisconsin, opened offices for the practice of medicine and surgery. A graduate of the Nebraska College of Medicine, Dr. Youngstrom has taken postgraduate work at the University of Wisconsin and at Henry Ford Hospital, Detroit, Michigan. Before moving to Zumbrota, he was associated with the Gunderson Clinic in La Crosse, Wisconsin.

* * *

Recently of Jacksonville, Illinois, Dr. Gladys Trommald has been appointed assistant superintendent of Anoka State Hospital, to serve with Dr. Edmund Miller, superintendent. Not new to Anoka, Dr. Trommald was on the staff of the Anoka State Hospital from 1936 to 1939. Since then she has taken postgraduate work in neurology and psychiatry at the University of Minnesota, has studied at the Wayne County training school in Northville, Michigan, and has been on the staff of the state hospital at Jacksonville, Illinois.

* * *

Guatemala vacations are the solution to winter's problems in the minds of two Minneapolis physicians. Dr. and Mrs. S. Marx White will leave Minneapolis on January 28 for a six-week vacation in Central America, with much of the time being spent in Guatemala. On February 14, Dr. and Mrs. Alfred T. Baker of Minneapolis will sail from New Orleans with a group of friends, planning to vacation for some time in Chichicastenango, an Indian village in the mountains of Guatemala.

* * *

Mental health problems in Minnesota were discussed by Dr. Alexander G. Dumas, assistant clinical professor of psychiatry at the University of Minnesota, at a meeting in Virginia on November 19 of the Virginia Branch of the American Association of University Women. The meeting was open to the public.

As medical director of the Minnesota Mental Hygiene Society, Dr. Dumas described the widespread extent of mental illness, the dearth of facilities and trained personnel for treating mental diseases, and the lack of public knowledge and understanding of mental illnesses.

* * *

At a meeting of the board of directors of Community Health Service, held in Minneapolis in November, Dr. Donald Hastings, head of psychiatry and neurology at the University of Minnesota, stated that top attention should be given to the training of the family physician in psychiatric science. One of his reasons was the fear that not enough psychiatrists would be trained in the next fifty years to meet the demand. The general practitioner, he said, is the "most important cog in the whole machine as far as helping the greatest number of emotionally upset people is concerned."

BETTER VISION — with MAY-O-LITE

It's an established fact that surface reflection is one of the biggest handicaps of those who wear glasses. Reflections produce "ghost images," confusion, and eyestrain.

By the application of Low Reflection Lens Coating to the surface of your lenses, 75 to 90% of these out-of-focus reflections are converted to useful transmitted light. This coating is harder than glass.

As a refractionist you are chiefly concerned with bettering the vision of your patients. In that interest, consider this information.

May-O-Lite Low Reflection Coating reduces surface reflection; eliminates out-of-focus 'ghost images'; hardens the the lens surface, thereby reducing surface scratches; improves image definition—lessens eye strain.

Each of these factors represents a possibility of better vision for your patients. You can investigate that possibility and explain it to your patients.

Low Reflection Lens Coating is available through most manufacturing and dispensing opticians. Write for a descriptive pamphlet and a treated sample of glass, today.

MAY RESEARCH

126 South Third Street
Minneapolis 1, Minnesota

In November, Dr. Ervin Pumala, formerly of Minneapolis, arrived in Warren to become a staff member of the Warren Clinic.

Dr. Pumala, a graduate of the University of Minnesota Medical School in 1940, served in the armed forces during the war, then began medical practice in Minneapolis. His major interest is in x-ray work and diagnosis.

In addition to Dr. Pumala, the staff of the Warren Clinic now includes Dr. C. H. Holmstrom, Dr. M. J. Bechtel and Dr. A. B. Nietfeld.

* * *

During the first week of December, Dr. J. D. Camp and Dr. P. F. H. Pugh, Rochester, were in Boston attending a meeting of the Radiological Society of North America. Dr. Camp presented a paper entitled "Chronic Idiopathic Hypertrophic Osteo-arthropathy," which was written in collaboration with Dr. Robert L. Scanlan, also of Rochester. Dr. Camp also presented an exhibit on "A Grid Front Casette: A Useful Application of the Stationary Grid" and gave two refresher courses entitled "Roentgenography of the Skull" and "Encephalography and Ventriculography." Dr. Pugh presented a refresher course on "The Examination of the Colon."

* * *

Unique in Minnesota was a cancer detection clinic held December 13 in Fergus Falls, with six Duluth physicians serving as department heads.

Housed in a school building, the clinic accommodated 400 residents of Fergus Falls and vicinity who had registered to be examined. Physicians of Fergus Falls assisted the Duluth specialists in conducting the clinic, which was co-sponsored by the Park Region District County Medical Society and the Minnesota Division of the American Cancer Society.

Clinic departmental heads from Duluth were Dr. Charles H. Mead, surgery; Dr. O. B. Patch, eye, ear, nose and throat; Dr. L. L. Merriman, internal medicine; Dr. M. G. Fredricks, dermatology; Dr. Russell J. Moe, gynecology, and Dr. Arthur H. Wells, pathology.

A technicolor motion picture, "The Traitor Within," was shown as part of a cancer lecture given by Dr. Wells, who is chairman of the cancer committee of the Minnesota State Medical Association. The lecture, held in connection with the cancer detection clinic, was open to the public.

* * *

Dedication of the "great hall" of the Mayo Foundation House as "Balfour Hall," in honor of Dr. Donald C. Balfour, director emeritus of the Mayo Foundation, took place at the annual business meeting of the Mayo Clinic staff on November 17. Dr. Balfour was presented with a scroll to commemorate the occasion by Dr. L. M. Randall, who represented the clinic staff.

At a ceremony on December 2, a life-sized oil portrait of Dr. Balfour was presented to the Mayo Foundation by the Association of Fellows of the Mayo Foundation.

* * *

Better training for physicians who plan to become general practitioners was emphasized by Minnesota physicians in their replies to a questionnaire sent out by the University of Minnesota's Department of Postgraduate Medical Education.

Preliminary results of the survey at the end of November also indicated that most physicians feel that one to five years of general practice would be of advantage to physicians before specializing, and that most men now in practice prefer a partnership or group-clinic type of practice. The physician who wanted his own individual practice, without even an assistant, was a rarity.

At the time that these results were announced by Dr. Thomas E. Eyres, who is in charge of the survey, more than one-third of the 2,900 questionnaires sent out had been returned. After completion and tabulation of the survey, which included numerous other queries, a final analysis of the results will be published by Dr. Eyres.

* * *

Appointment of Dr. Francis F. Callahan, Pine City, as chief of the medical services of the State Division of Social Welfare, was announced December 13 by Jarle Leirfallom, director.

Succeeding Dr. Edwin J. Simons, Swanville, who resigned in October, Dr. Callahan is responsible for planning and programming the state crippled children services and the institutional control of tuberculosis in the state, and for the administration of the state sanatorium at Walker. He also acts as medical consultant of county welfare agencies throughout the state.

Dr. Callahan, a graduate of the University of Maryland in 1913, has specialized in tuberculosis work since 1916. He was medical director of Pokegama Sanatorium from 1919 to 1942, when he became superintendent of the state sanatorium at Walker. In 1946 he resigned as superintendent to enter private practice in Saint Paul.

* * *

A five-man committee to direct a radio-isotope research program at Minneapolis Veterans Hospital has been appointed by Dr. Harold S. Diehl, chairman of a committee on medical education for the Veterans Administration.

Heading the new committee as chairman is Dr. Wallace Armstrong, chief of the Department of Physiological Chemistry in the University of Minnesota Medical School. The other four members of the committee are Dr. John Tate, University professor of physics; Dr. Samuel Nesbit, Veterans Hospital physician; Dr. Howard Horns, of the University's Department of Medicine, and Dr. Karl Stenstrom, professor of biophysics at the University.

The Veterans Administration has made $25,000 available to establish the program in Minneapolis. Radioisotopes will be obtained from the Atomic Energy Commission.

225 Sheridan Road **Medical Director** **Phone Winnetka 211**

After retiring from practice in 1942, Dr. N. O. Pearce, Minneapolis, is again leading an active medical life.

Recently appointed director of the Division of Cancer Control, Minnesota Department of Health, Dr. Pearce has a long history of medical work in Minnesota. After graduating from the University of Minnesota Medical School in 1905, he practiced in Hibbing until 1914, when he accepted a teaching position in pediatrics at the University. In 1918 he returned to private practice in pediatrics and continued in that field in Minneapolis until 1934. He then practiced for eight years in Miami, Florida, finally retiring in 1942. Shortly after that he found himself engaged in supervisory work with the Minnesota Department of Health, upon the invitation of its executive officer, Dr. A. J. Chesley.

Today, under the direction of Dr. Pearce, the Division of Cancer Control is correlating and co-ordinating the work of medical groups concerned with the control of cancer. For Dr. Pearce, retirement is now a thing of the past.

* * *

After twenty years of practice in Elmore, Dr. Arno W. Sommer will close his office and move to Temple, Texas, to become radiologist with the Scott White Clinic.

The Elmore practice is being taken over by Dr. Harry Shragg, formerly of Minneapolis, and Dr. Troy Rollins, formerly of Blue Earth.

Before moving to Elmore in 1927, Dr. Sommer received his medical training at the University of Minnesota, interned at the Northern Pacific Railroad Hospital, and studied at St. Paul and Swedish Hospitals in the Twin Cities. While in Elmore, he was active in many civic organizations and at one time was president of the Elmore Board of Education.

The successors to his practice, Dr. Shragg and Dr. Rollins, studied medicine at the University of Minnesota Medical School. Dr. Rollins is now interning at Minneapolis General Hospital. Dr. Shragg took over the practice in Elmore on January 1; he will be joined by Dr. Rollins in July.

* * *

"After-effects of the atom bomb have been exaggerated," stated Dr. Irving McQuarrie, head of the University of Minnesota's Department of Pediatrics, when he returned December 15 from a three-month study of medical education, research and hospitals in Japan.

"I found cases of persons suffering from scars and anemia," he said, "but their numbers were not as great nor their condition as serious as we had been led to expect."

Since many hospitals and medical centers had been housed in buildings built to withstand earthquakes, they stood up quite well against wartime bombings, Dr. McQuarrie said.

He found that Japan's health is impaired by inadequately trained physicians and by approximately 80,000 "quacks" who practice blood-letting. Many of the

"physicians" were students hurriedly trained as a wartime emergency, who are now being returned to medical schools for another year, to be followed by a period of internship.

Dr. McQuarrie went to Japan for the three-month study at the request of the Rockefeller Foundation.

According to a recent announcement, the National Cancer Institute of the United States Public Health Service has awarded nearly $750,000 in forty-six grants for clinical and basic biological research.

The Pasteur Institute of Paris and the Hebrew Institute in Palestine are among those receiving grants. For the first time, the National Advisory Cancer Council, composed of outstanding cancer specialists of the country, has made grants to agencies outside the United States.

The University of Minnesota has been awarded three grants: one to Dr. George E. Moore to investigate the use of fluorescein dyes in the detection of malignant tissue; one to Dr. David Glick to make histochemical studies on the stomach in relation to cancer; and one to Dr. Owen H. Wangensteen to attempt to identify a precursor group in gastric cancer.

In addition, twenty-six medical schools have been awarded grants totalling $593,130 for the improvement of cancer teaching, and $132,645 for cancer control projects. An additional grant of $250,000, contingent on the securing of additional funds totalling $650,000, was made to the Roscoe B. Jackson Memorial Laboratory in Bar Harbor, Maine, for replacing the laboratory which was destroyed by fire last fall.

Previously, all state departments of health had been allocated sums totalling $2,500,000 for cancer control projects.

Allotments were made out of the United States Public Health Service funds.

HOSPITAL NEWS

It was announced on November 20 that the Mankato city council had approved the recommendation of Dr. A. F. Kemp, city health officer, to supply oxygen equipment for the Mankato Detention Hospital. It was estimated that the equipment would cost $150 to $200.

* * *

Possible future expansion of the Spring Grove Hospital was provided for in November when the hospital board of directors decided unanimously to purchase an additional lot adjacent to the present hospital grounds. Included among the members of the board of directors is Dr. J. W. Helland, Spring Grove.

* * *

On November 23 it was announced that Miller Hospital in Saint Paul planned to start the Charles T. Miller School of Practical Nursing. Dr. Peter Ward, administrative director of the hospital, in making the announcement, stated that the school would offer a one-year course in various aspects of nursing and would be

The need for a community hospital in Stewartville, Olmsted County, was reviewed by Dr. William F. Braasch, Rochester, early in November at a meeting of the Stewartville Community Club.

Pointing out that the nearest hospital was forty miles away in Rochester, Dr. Braasch stated, "It is astounding that there has never been a community hospital here before. The need is so great that steps should be taken at once. . . . Construction should begin next spring—and no later."

He stated that only 20 per cent of illnesses required highly specialized care and that a community hospital would better serve the moderate income group, the old age group and the laborer who may have a minor injury or illness.

Illus. Price, $11.00, cloth. Philadelphia: Lea & Febiger, 1947.

DISEASES OF THE NOSE, THROAT AND EAR. Ninth Edition. William Lincoln Ballenger, M.D., F.A.C.S. Late Professor, School of Medicine, University of Illinois; and Howard Charles Ballenger, M.D., F.A.C.S., Associate Professor and Acting Chairman of the Department of Otolaryngology, Northwestern University School of Medicine, Chicago. Assisted by John Jacob Ballenger, B.S., M.D., Research Fellow in Otolaryngology, Northwestern University School of Medicine, Chicago. 993 pages. Illus. Price, $12.50, cloth. Philadelphia: Lea & Febiger, 1947.

A PRIMER OF CARDIOLOGY. George E. Burch, M.D., F.A.C.P. Associate Professor of Medicine, Tulane University School of Medicine; Senior Visiting Physician, Charity Hospital; Consultant in Cardiovascular Diseases, Ochsner Clinic; and Paul Reaser, M.D., Instructor in Medicine, Tulane University School of Medicine; Assistant Visiting Physician, Charity Hospital, New Orleans. 272 pages. Illus. Price, $4.50, cloth. Philadelphia: Lea & Febiger, 1947.

PRACTICAL X-RAY TREATMENT. Arthur W. Erskine, M.D. Chief radiologist, St. Luke's Methodist Hospital and Mercy Hospital, Cedar Rapids, Iowa; past Chairman of Section on Radiology of the AMA. Third edition. 156 pages. Illus. Price, $4.50, cloth. Saint Paul and Minneapolis: Bruce Publishing Company, 1947.

The author has once more revised and brought up to date his excellent book on x-ray treatment, partly in the light of continuing developments in the art but particularly in the light of his own large experience in an active radiation-therapy practice. The new edition, as was the

case with the previous two editions, shows how one successful radiation therapist uses roentgen therapy and, to some extent also, radium therapy. Dr. Erskine shows how better results can be realized from the equipment at one's disposal by attention to a proper power supply, to safety measures, and to accuracy in calibration, both as to quality and quantity. He stresses intelligence and skill in the planning of treatment for the particular case, with especially careful use of the now readily available and reliable depth distribution data, an adequate range of which is included in the book—either assembled for easy reference from other sources, or, where necessary, modified without loss of validity to suit his own particular requirements.

The author feels that there should be as much standardization and simplification as possible of the various voltages, filtrations, target-field distances, et cetera, that are employed, and he confines himself to practically only two voltages, 135 and 200 kvp. Of course, in view of the necessary use of several different filtrations and target-skin distances for each voltage, a considerable number of intensity and distribution tables are therefore still necessary.

Attention is called to the probable fact that there is no difference in the biological effect of different wavelengths, provided the same actual dose is absorbed, and that the only need for different penetrations, therefore, is the ability to get the radiation to where it is needed, with the least possible effect superficial to the area which one desires to treat. Though he does not use supervoltage equipment, the author rightly believes that the only reason for using very high voltages would be the high percentage depth doses obtained, but that this type of therapy is uneconomical because of the higher cost involved.

In the chapter on skin diseases the treatment of the various hemangiomata and vascular nevi is more elaborated than in the previous edition. Since the advent of shockproof tubes, x-ray treatment is preferred to radium for treatment of the vascular nevi. However, care must be used in the treatment of vascular tumors near epiphyses of infants, to avoid interference with growth.

Skin cancer is now included in the chapter on malignant tumors—a more logical arrangement.

Infections, such as erysipelas, palmar abscess, felon, postoperative parotitis, sinusitis, virus pneumonia, gas bacillus infection, arthritis of some types, which are effectively treated by irradiation are discussed in a separate chapter.

Other nonmalignant conditions, such as hyperthyroidism, tuberculous lymph nodes, uterine hemorrhage and fibroid tumors, are covered quite adequately for the size of the volume.

The relation of the radiologist to the cancer problem is treated in a separate chapter and is discussed more fully than in the previous editions.

Cancer of the various organs is, in some cases, discussed more extensively, especially transvaginal x-ray treatment of cancer of the cervix, which the author prefers to radium whenever it can be efficiently applied, as the uniformity and adequacy of deep dosage exceed that of the best radium technique.

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

In cancer of the breast, Dr. Erskine believes that operable cases should be treated surgically. He advocates preoperative irradiation, provided that shrinkage, and perhaps disappearance, of the tumor does not lead to abandonment of surgery. Postoperative therapy can increase the five-year surgical survivals about 10 per cent when the involvement is limited to the breast, and about 25 per cent when axillary metastases are present.

Hodgkin's disease, lymphosarcoma and leukemia are also discussed in the chapter on malignant conditions.

All in all, this is a useful book for anyone doing radiation therapy. The new volume is a definite modernization of the now eleven-year-old second edition, which had five reprintings.

EDWARD SCHONS, M.D.

THE YEARS AFTER FIFTY. By Wingate Johnson, M.D., Professor of Clinical Medicine and Chief of Private Diagnostic Clinic, Bowman Gray School of Medicine of Wake Forest College; Recent Appointee, Board of Trustees, the AMA. New York: Whittlesey House, McGraw-Hill Book Company, Inc. Price $2.00.

This short booklet will provide a very satisfactory evening's reading for any doctor with any degree whatever of geriatic understanding. It has some informative reading matter, which we may suggest or provide for many patients, for whom guidance in "growing old gracefully" has many advantages.

The author quotes avidly and well, and captions each well-devised chapter by inspiring excerpts from ageless literature. He draws all the way from Plato, Cicero and Saint Paul through Shakespeare, Samuel Johnson and Osler to Alvarez, Cowdry and Stieglitz. Needless to say, this philosophical connotation (as implied when Job laments, or Paul exults) dominates where the general purpose is to catalogue why the longer life of accomplishment and travail yields so abundantly in comparison to the life of speed and merriment.

It might be stated that the book is almost too concise to yield adequate information on the many subjects covered; perhaps it has been written and will best suffice as an introduction for those who will seek more information in the countless sources now easily available. The author writes as a wise and experienced internist, giving his impressions of what medicine now offers, to promote the comfort and usefulness of the ever-increasing group of our citizenry living beyond sixty years. The

problem as to numbers may be sensed by this one quotation: "Statistics show that between 1930 and 1940, the total population of the United States gained only 7.2 per cent, while the number of people of sixty-five years or older increased by 35 per cent. It has been estimated that by 1960, the average life expectancy in the United States should reach 75 years." Every thoughtful person must begin to weigh in the balance what this means in our political, economic, educational and social developments. This is a useful book.

E. L. TUOHY, M.D.

SYNOPSIS OF ALLERGY. Second Edition. Harry L. Alexander, A.B., M.D., Professor of Clinical Medicine, Washington University, School of Medicine, St. Louis; Editor of *The Journal of Allergy*. 255 pages. Illus. Price, $3.50. St. Louis: C. V. Mosby Company, 1947.

Certified as an allergist by the American Board of Internal Medicine in 1938 and enrolled as an active member in several national allergy associations, Dr. Alexander is well qualified to write this Synopsis of Allergy, of which this is the second edition. The first edition was published in 1941.

The contents cover history, atopy, bronchial asthma, hay fever, atopic rhinitis, gastrointestinal allergy, headache, conjunctivitis and other atopic disorders, allergic dermatoses, physical allergy, drug allergy, serum allergy, bacterial allergy, and vascular allergy. At the end is an appendix, which gives briefly, tests, diagnostic methods, elimination diets, et cetera, and a bibliography, which includes eighty-five references to books and journals.

The author gives a good, concise review of his subject, though it is too brief in its consideration of physical and emotional factors as they affect the allergic individual.

In format and type the book is similar to all the books in the Mosby Synopsis Series.

Florence Nightingale 1820-1910

NINETY YEARS AGO, at the St. Thomas hospital in England, Florence Nightingale founded her first nursing school. Although it is probable that this great humanitarian was not the first to recognize the need for trained nurses to assist the doctor and the patient—her name will long be remembered as the first to effectively fulfill this need. Her contribution to the advance of medical science was indeed a great one.

Today, just as in Florence Nightingale's time, there exists an acute shortage of nurses. You, Doctor—perhaps more than any other one person—can help to alleviate this shortage. As a representative of the medical profession, you can best provide the suggestion to prospective nurses in your community. An increased number of trainees must find its way to the nursing schools if the current shortage is to be remedied.

Glenwood Hills Hospitals through its school of nursing, is proud to take part in this effort. Glenwood Hills' graduates have had "care of the patient" and "service to the doctor" stressed to them. In addition to the instruction necessary to perform their duties, they are well equipped with a knowledge of the true purpose of nursing. We respectfully request that you have prospective nurses in your acquaintance investigate our facilities.

CLASSES BEGIN IN JANUARY, JUNE AND SEPTEMBER

★

Candidates for the June class should make reservations at this time. School and health records must be reviewed and correspondence completed prior to acceptance.

SCHOOL OF PSYCHIATRIC NURSING

A one-year course is offered to girls over 17 years of age. High school graduation is necessary to admission. Tuition is free. For full information write Glenwood Hills Hospitals, School of Nursing, Helen A. Rascop, R.N., Superintendent of Nurses.

SHOULD VITAMIN D BE GIVEN ONLY TO INFANTS?

VITAMIN D has been so successful in preventing rickets during infancy that there has been little emphasis on continuing its use after the second year.

But now a careful histologic study has been made which reveals a startlingly high incidence of rickets in children 2 to 14 years old. Follis, Jackson, Eliot, and Park* report that postmortem examination of 230 children of this age group showed the total prevalence of rickets to be 46.5%.

Rachitic changes were present as late as the fourteenth year, and the incidence was higher among children dying from acute disease than in those dying of chronic disease.

The authors conclude, "We doubt if slight degrees of rickets, such as we found in many of our children, interfere with health and development, but our studies as a whole afford reason to prolong administration of vitamin D to the age limit of our study, the fourteenth year, and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."

*R. H. Follis, D. Jackson, M. M. Eliot, and E. A. Park: Prevalence of rickets in children between two and fourteen years of age, Am. J. Dis. Child. 66:1-11, July 1943.

MEAD'S Oleum Percomorphum With Other Fish-Liver Oils and Viosterol is a potent source of vitamins A and D, which is well taken by older children because it can be given in small dosage or capsule form. This ease of administration favors continued year-round use, including periods of illness.

MEAD'S Oleum Percomorphum furnishes 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10- and 50-c.c. bottles and bottles of 50 and 250 capsules. Ethically marketed.

MEAD JOHNSON & COMPANY, Evansville 21, Ind., U.S.A.

This rather startling statement comes from recognized authorities in the vitamin field. There is no doubt of its validity, since it is based upon competent investigators' prolonged observation of all types of patients, including detailed study of their diets.

It seems that a great part of our population has not learned *what* and *how* to eat in spite of the extensive educational efforts of the medical profession. The "sandwich and pie diet," the "quick lunch" and over-indulgence in refined carbohydrates not only fail to contribute riboflavin and other B complex vitamins, but also increase the need for these accessory factors

Where such dietary habits are firmly entrenched and cannot or will not be changed, the realities of the situation necessitate vitamin supplementation for protection.

Parke-Davis VITAMINS

For more than thirty-one years Parke-Davis has pioneered in the discovery, standardization and development of vitamin products. From among the many Parke-Davis vitamin preparations—supplementary and therapeutic—one or more can be readily chosen to fit every patient's need.

DISTINCTIVE

ESTINYL* (ethinyl estradiol) is distinctive among oral estrogens.

Ethinyl estradiol is a derivative of the true follicular hormone, alpha-estradiol. It is more potent, milligram for milligram, than any other oral estrogen, natural or synthetic, in clinical use today.

It induces that therapeutically important "sense of well-being" characteristic of the natural estrogens. Its cost is low, making it available to all women.

It offers the convenience of estrogen therapy by mouth; and provides relief with a rapidity almost equal to parenteral hormone treatment.

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

ESTINYL

(ethinyl estradiol)

DOSAGE: One ESTINYL Tablet of 0.05 mg. daily. In severe cases two to three tablets may be prescribed daily and dosage reduced as symptoms are alleviated.

ESTINYL (ethinyl estradiol) Tablets of 0.05 mg. (pink) and 0.02 mg. (buff), in bottles of 100, 250 and 1,000. ESTINYL Liquid, 0.03 mg. per 4 cc., in bottles of 4 and 16 oz.

Experience is the

best teacher

It's true in cigarettes too!

MORE PEOPLE ARE SMOKING CAMELS THAN EVER BEFORE

YES, experience *is* the best teacher in choosing a cigarette. And with millions of smokers who have tried and compared different brands of cigarettes, Camels are the "choice of experience."

Try Camels yourself. See how the full, rich flavor of Camel's choice, properly aged and blended tobaccos pleases your taste. See if Camel's cool, cool mildness isn't mighty welcome to your throat.

Let your own experience tell you why more people are smoking Camels than ever before.

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS THAN ANY OTHER CIGARETTE

The makers of Camels are understandably proud of the fact that so many, many doctors prefer Camels as the cigarette for their personal enjoyment.

In a nationwide survey by three independent research organizations, 113,597 doctors were asked to name the cigarette they smoked. More doctors named Camel than any other brand.

Dietary Supplementation

MORE THAN ISOLATED NUTRIENTS

The observation that nutritional deficiencies rarely occur singly, and the fact that individual nutrients are not metabolized by themselves but in conjunction with others, are both well established. Hence dietary supplementation—in order to be effective—must provide more than merely isolated nutrients.

The dietary supplement of Ovaltine and milk presents a rational mixture of essential nutrients of wide clinical applicability. It supplies not only B complex vitamins, but also ascorbic acid, the fat soluble vitamins A and D, biologically complete protein, and readily utilizable caloric food energy in the form of fat and carbohydrate.

This dietary supplement is especially useful to compensate for the inadequacies of a deficient diet, and is valuable when given in conjunction with specific nutrients when specific deficiencies are detected. Easily digested and of low curd tension, it presents no undue digestive burden.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Ovaltine

Three servings daily of Ovaltine, each made of
½ oz. of Ovaltine and 8 oz. of whole milk,* provide:

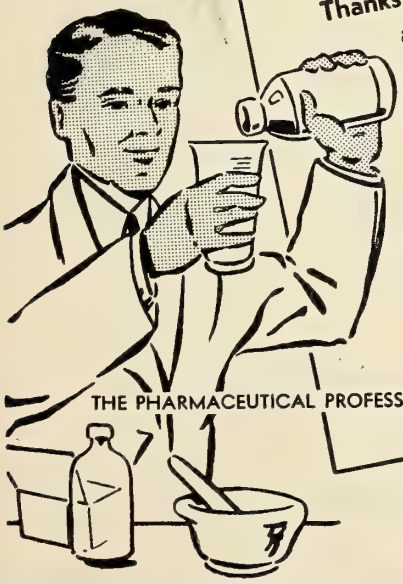
CALORIES	669	VITAMIN A	3000 I.U.
PROTEIN	32.1 Gm.	VITAMIN B_1	1.16 mg.
FAT	31.5 Gm.	RIBOFLAVIN	2.00 mg.
CARBOHYDRATE	64.8 Gm.	NIACIN	6.8 mg.
CALCIUM	1.12 Gm.	VITAMIN C	30.0 mg.
PHOSPHORUS	0.94 Gm.	VITAMIN D	417 I.U.
IRON	12.0 mg.	COPPER	0.50 mg.

*Based on average reported values for milk.

THE MEDICAL PROFESSION

Dorsey

SPONSORS of our Maturity



"GROWING UP" implies far more than gaining height and adding years. It means acquiring competence, assuming responsibility, forming a circle of friends, attaining maturity.

In the forty years from 1908 to 1948, The Smith-Dorsey Company has been steadily "growing up"—but not by our own efforts alone.

Our growth has been sponsored by our constantly growing circle of friends in the medical and pharmaceutical professions.

Thanks to your loyal encouragement and patronage, we are today able to repay our sponsors with excellent service and high standard products assured by a new research and manufacturing plant . . . increased research grants . . . added research personnel . . . two new branch offices and shipping warehouses . . . added medical service representation.

The First Modern Surgery...

Both Medicine and Dentistry thank the French surgeon, Ambroise Paré (1510-1590), for controlling hemorrhage with a simple ligature for large arteries, rather than with a salamander full of barbaric cautery irons. (He also was virtually the first to speak of dental "nerves" and replanting.)

In mitigating bloodflow, which often meant a surgeon's handicap and a patient's death, Paré made possible more major surgery—and, with his "Bec de Corbin," illustrated above, spurred it on toward the hemostat of Dr. Spencer Wells, who died only two years before our company was founded. (Also, if less directly, toward anesthesia and asepsis.)

Doctors' legal liability had been evolving for 3,600 years. But in Paré's own lifetime there dawned the broader field of medical jurisprudence (forensic medicine), embracing *all* factors which bring the doctor into contact with the law. And Paré gave much to the art of drawing up medico-legal reports.

CLAIMS

VS.

DIFFERENCES

WHAT value have claims of superiority unless there is a difference in formula or process to justify such claims?

Take cigarettes for example.

PHILIP MORRIS Cigarettes are *made* differently. In the clinic as well as in the laboratory, the *advantages* of PHILIP MORRIS have been repeatedly observed, repeatedly reported by *recognized authorities* in leading medical journals. Yes, PHILIP MORRIS *claims* superiority . . . *and that superiority has been proved.**

May we suggest that your patients suffering from irritation of the nose and throat due to smoking change to PHILIP MORRIS—*the one cigarette proved definitely less irritating.*

Laboratory studies on sperm-immobilizing power and clinical studies on occlusive action and safety establish that "RAMSES"* Vaginal Jelly affords the optimum protection that a jelly alone can provide. For example.

- It will immobilize sperm in the fastest time recognizable under the Brown and Gamble method.
- It will occlude the cervix for as long as 10 hours after coitus.
- It will not liquefy or run at body temperature.
- It does not separate.
- It is nonirritating and nontoxic.

For optimum protection when dependence must be placed on jelly alone, specify "RAMSES" Vaginal Jelly.

Active Ingredients: Dodecaethyleneglycol Monolaurate 5%; Boric Acid 1%; Alcohol 5%.

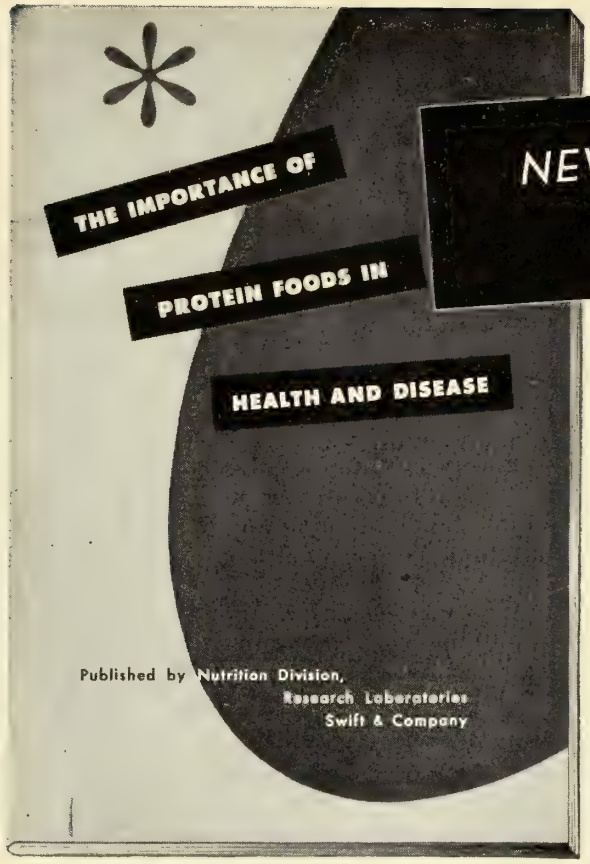
FOR THE MEDICAL PROFESSION

No Calculations • No Calibrations Necessary • No Standards Need be Prepared

The Leitz Pre-Calibrated Photo-Electric Clinical Colorimeter is ready for use when received. A handbook supplied with the instrument contains calibrations for 38 different clinical chemistry determinations including all standard determinations (see List).

Operation of the Leitz Colorimeter is quick and simple. After presetting the instrument the unknown is inserted and the reading on the meter noted . . . The calibration table in the special handbook indicates the concentration of the unknown. Variations encountered in visual color matching are completely eliminated. Identical readings on a specimen, by different laboratory workers, are possible.



This simplicity and convenience of operation is combined with the precision and sturdiness associated with Leitz instruments. Each Leitz Photo-Electric Colorimeter is individually calibrated. A high degree of accuracy is maintained in calibrating and preparing the final tables. Booklet No. 1323 giving complete information is available without charge.

The Leitz Colorimeter is calibrated for these determinations:

- Acid Phosphatase
- Albumin in Urine
- Bilirubin
- Blood Amylase
- Blood Thiocyanates
- Bromsulphalein Liver Function
- Calcium in Serum
- Cholesterol Esters
- Cholesterol in Serum
- Creatinine in Blood
- Glucose in Blood
- Glucose-Micro Method
- Hemoglobin
- Icterus Index
- Non-Protein Nitrogen
- Phenolsulfonphthalein Kidney Function Test
- Plasma CO2 Capacity
- Serum Albumin
- Serum Bromides
- Serum Chloride
- Serum Globulin
- Serum Inorganic Phosphate
- Serum Phosphatase
- Serum Protein
- Spinal Fluid Protein
- Spinal Fluid Sugar
- Sugar in Urine
- Sulfadiazine
- Sulfaguanidine
- Sulfanilamide
- Sulfapyridine
- Sulfathiazole
- Sulfamerazine
- Sulfasauxidine
- Urea Nitrogen in Blood
- Urea Nitrogen in Urine
- Uric Acid in Blood
- Urine Chloride

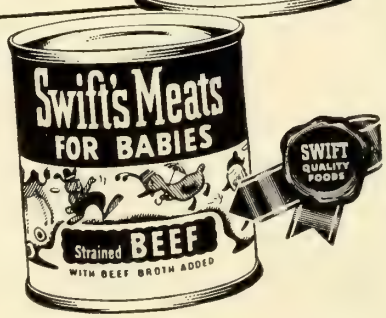
NEW . . . physician's handbook of protein-feeding

"The Importance of Protein Foods in Health and Disease"



Free — let us send you a copy now

Written by a practicing physician, in conjunction with the Nutrition Division of Swift & Company, this booklet provides a convenient source of reference for all the important, new, published findings concerning the value of protein in the human diet.

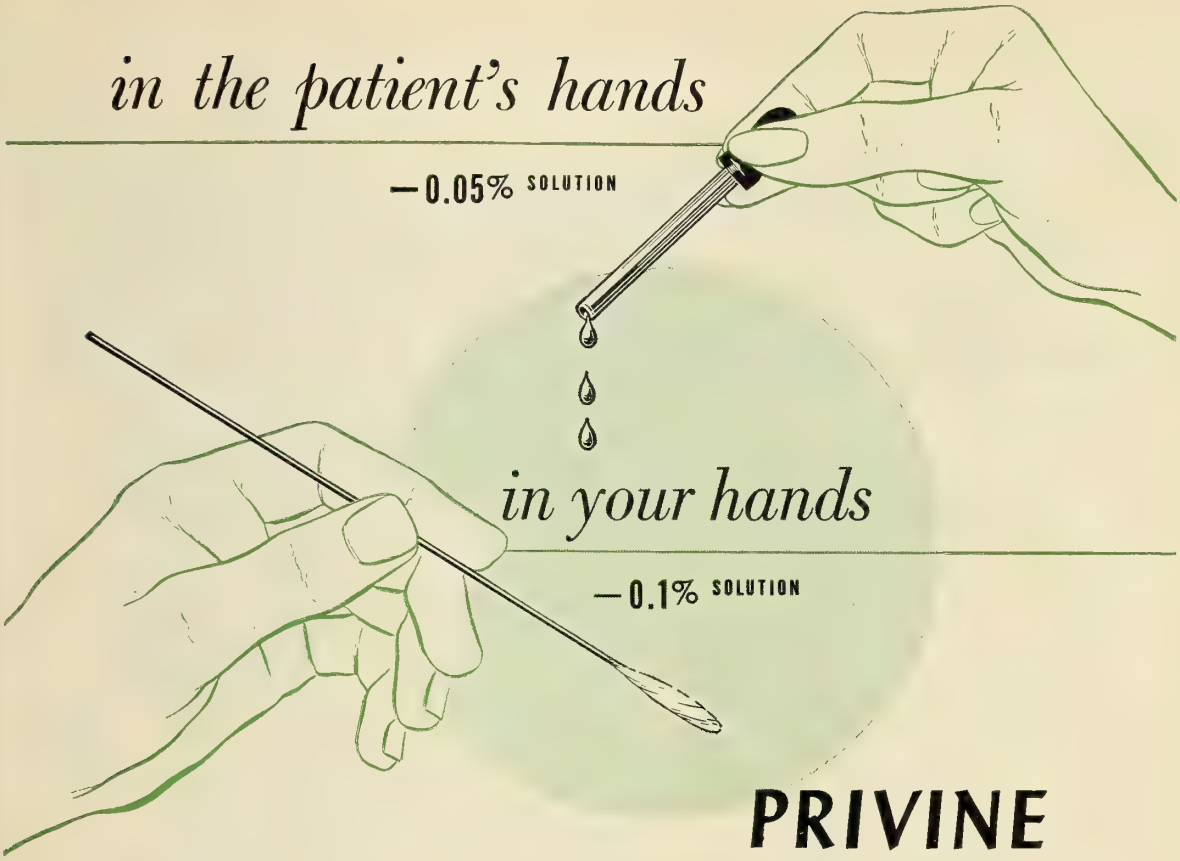
The booklet is broad in its scope, covering the subject from *the general significance of protein in nutrition* to specific *clinical aspects*. In addition, high-caloric, high-protein diets—for both oral and tube-feeding—are included. "The Importance of Protein Foods in Health and Disease" provides a practical, working handbook of protein feeding. Let us send you your copy now. Simply write Swift & Company, Dept. S.M.B., Chicago 9, Illinois.

Also Swift's Diced Meats . . . where textures of foods indicated may be less fine, you may find these tender, juicy cubes of meat desirable.

ACCEPTED COUNCIL ON FOODS AND NUTRITION AMERICAN MEDICAL ASSOCIATION

All nutritional statements made in this advertisement are accepted by the Council on Foods and Nutrition of the American Medical Association.

Palatable answer to many problems of protein supplementation



The new Swift's Strained Meats are being used more and more in soft diets where a high-protein intake is indicated. The six kinds of Swift's Strained Meats—beef, lamb, pork, veal, liver and heart—provide an exceptionally palatable source of *complete, high-quality proteins*, B vitamins and iron. Developed originally for infants, Swift's Strained Meats are 100% meat, soft and fine in texture—easily adaptable to tube-feeding.

The booklet "The Importance of Protein Foods in Health and Disease" is accompanied by a supplementary pamphlet containing simplified high-protein diets, for both oral and tube-feeding, using Swift's Strained Meats. Send for your copy today.

PRIVINE

PRIVINE hydrochloride, 0.05 per cent, is sufficiently potent to produce long-lasting relief in the average case of nasal congestion in patients of all ages. It is therefore the Privine preparation of choice for regular prescription purposes.

Privine hydrochloride, 0.1 per cent, fills the need for an agent which will produce the intense vasoconstriction frequently necessary for adequate visualization and for pre- and post-operative shrinkage. It is therefore the Privine preparation of choice for direct use in the office or hospital.

When properly administered, Privine hydrochloride induces prolonged vasoconstriction with relative freedom from local or general side effects. Three drops will usually produce nasal decongestion lasting 3–6 hours. Overdosage should be avoided.

Issued: 0.05%, bottles of 1 fl. oz. and 16 fl. ozs. • Jelly, 0.05%, tubes of 20 Gm.
0.1%, bottles of 16 fl. ozs. only

A NEW APPLIANCE
THAT CLEANS BY WASHING THE AIR

Home economists who use and recommend Rexair have called it "the greatest advance in home cleaning methods in thirty years." Rexair cleans by *washing* dust from the air you breathe.

Rexair's powerful suction picks up dirt from carpets, furniture, walls and bare floors. This dust-laden air is carried completely through a water bath. Clean water-washed air is discharged back into the room.

There is no porous bag, screen, or filter on Rexair. No way for dust to escape after it has been trapped in Rexair's water bath. No layer of dust on the furniture such as follows old-fashioned methods of cleaning. Rexair actually cleans *clean!*

This is why so many allergists and other physicians prefer Rexair, for their homes and offices, and for their patients. Rexair, and only Rexair, uses a bath of pure water to trap and hold dust.

SEND FOR THIS FREE BOOK!

Learn more about Rexair! Send for this free, illustrated 12-page book. Shows how Rexair does dozens of household jobs, how it even cleans the air you breathe. Ask for as many copies as you need.

PRENATAL SUPPORTS

CAMP

Of the so-called minor complaints of pregnancy, a contributor to the medical literature* makes the following statement concerning backache—

"Backache seemed to be due to several causes. Strain of the lumbar muscles and the vertebral ligaments, due to a change in the center of gravity was often responsible; fallen arches aggravated the complaint. It was relieved by rest in bed. A maternity corset with moderately rigid stays in the back was of benefit . . . Sacro-iliac relaxation as evidenced by pain over the joint was usually unilateral and was referred along the sciatic nerve. Usually a maternity corset would relieve it. This corset should have a strap or other device that will pull it snug over the sacro-iliac region."

Charles J. Marshall New York Journal of Medicine, Vol. 34, Aug. 15, 1934

Camp prenatal supports are unique in that the overstrap with its buckle (through which the lacings ply) allows the support to be drawn evenly and firmly about the pelvis; thus the pelvic joints are protected and steadied.

From such a foundation, the back of the patient is well supported and the abdominal muscles are aided in holding the increasing load in position.

THE EARLY YEARS OF ANDREAS VESALIUS

JOHN F. FULTON, M.D.

Sterling Professor of Physiology, Yale University School of Medicine
New Haven, Connecticut

Preliminary Remarks

I count it a special privilege to be invited to address the members of the Ramsey County Medical Society on the occasion of the fiftieth anniversary of its library, for I have an abiding interest in medical libraries and firmly believe in the importance of their potential contribution to the medical profession; not only this, but I have a particular familial interest in this library since in the early days my father was one of its more ardent advocates, and my uncle, Dr. Charles Wheaton, was also a staunch supporter. Thus if I were not interested in it myself, I should be guilty of filial disrespect.

Father, who was president of the Ramsey County Society in 1893 and of the State Association in 1897-98, had settled in Saint Paul in 1882, and there is one innovation which he introduced in the state of which my family have always been especially proud. In 1884 the dean of the Minnesota College Hospital announced that the professor of ophthalmology and otology would "give a free clinic on diseases of the eye and ear at the college building upon each Friday, and that all indigent afflicted are invited to avail themselves of the attention now for the first time in the history of our state offered them."* This, I believe, marked the beginning of dispensary service in Minnesota. Father always contended that he learned more about ophthalmology from his dispensary than he did from his office practice. As a result, he was at all times very insistent that young medical graduates should make a point of giving some part of their time to dispensary practice.

ANDREAS VESALIUS

SIR William Osler always maintained that no medical library could possibly afford to be without a copy of the great masterpiece of anatomy, the *Fabrica* of Andreas Vesalius published in 1543. So successful was his teaching that few libraries can now afford to have one, if they didn't acquire it before Osler's rapidly multiplying progeny of medical book collectors were turned loose upon an unsuspecting world.

There is just reason, however, for Osler's contention about the importance of the *Fabrica* since there are few parallels in history to the prodigious and precocious labors of the restless young Belgian whom the late Edward Streeter used to call "the redhaired man of wrath." Like his distinguished Roman predecessor, Galen, Vesalius was incredibly industrious, but he was also vain, short-tempered, and must have been anything but comfortable to live with. Indeed, he once said that anyone who would follow the medical profession must not take unto himself a wife.

Born at the turn of the year 1514-1515 of an English mother, Isabella Crabbe, and a pharmacist father (also named Andreas Vesalius), who was descended from a long line of physicians, Andreas the younger exhibited signs of precocity early in life, and it is recorded that before the age of ten he began to collect objects of natural history and to dissect rats and moles; later he devel-

Read at the fiftieth anniversary celebration of the Ramsey County Medical Society Library, Saint Paul, Minnesota, September 23, 1947.

*Northwestern Lancet, 3:183, (May 15) 1884. See also R. O. Beard's "The History of Medical Education in the State of Minnesota" in *The Unification of Medical Teaching in the State of Minnesota. An Historical Evening.* December 8, 1908 (Privately printed). 88 pp. (p. 27).

oped a similar passion for human dissections. On one occasion, when a student at Louvain, he smuggled through the gates of the city at night the skeleton of a robber who had been executed on a gibbet; and when he had articulated the completed skeleton in his rooms, he dared demonstrate it to his friends. But these activities soon were discovered and he was in consequence forced to flee Louvain.

This courageous searching for the truth in an age of superstition and slavish adherence to the past made him a marked man, and it must partially account for the fact that when only twenty-two years of age he was appointed professor of anatomy at the University of Padua. But before going to Padua he had first studied at Paris, where his crusading spirit led him almost at once into conflict with authority. Quoting the tag from Emerson that "Universities are hostile to genius," Edward Streeter adds that Emerson might have cited the University of Paris and Vesalius to prove his point. "For here was a genius who had articled with destiny to dedicate himself, his gifts, his splendid impatience to Reform; and here a University so encrusted and ankylosed with Conservatism that there was nothing quite like it in Europe at the time. What was Vesalius doing in that high, hushed Temple of Authority, that Depot of Bigotry, where studies in the schools had subserved the Faith for twelve generations and more? Did he hope at nineteen, by some open process, to supple the hard unintelligence that reigned in those schools, 'so great, so rich, so *rigid*' (as Rabelais describes them), where, if a scholar dares pronounce *quisquis* or *qualis* in other than the medieval manner he is like to be stripped of his dignities?"[6]

Vesalius had matriculated in medicine at Paris in 1533, and despite his brushes with the faculty he continued to work for the next three years, fulfilling the requirements for a doctoral degree. Had it not been for the threat of war between France and the Imperial forces of Charles V, to whom Vesalius and his family were closely tied, he would have taken his degree; but he returned to Louvain without it. His two masters, Jacobus Sylvius and Guenther von Andernach, were impatient with their doubting pupil, so much so that Sylvius, before Vesalius finally departed, became so enraged with him that he would probably have opposed the awarding of his degree. To quote Streeter once again in reference to these years in Paris:[6]

> The tough hearts of those who pioneer grow tougher under disappointments. Vesalius was galvanized into action. He plotted to end those traffickings with the seven types of lower animals which Galen allowed as substitutes, and to humanize the study-material at Trinquet. At the risk of his life he made forays to the gibbets of Montfauçon and the graves in the Cemetery of the Innocents.
>
> "I acknowledge no authority save the witness of my own eyes," said this champion of the *visum et repertum* method. "I want liberty to compare the dicta of Galen (Prince of Physicians!) with the tangible facts of bodily structure." He labored constantly to improve the technique of dissection; he tells how he thrust aside the bungling barbitonsors who, he says, "had made a mess of the eight muscles of the abdomen which they exposed in torn and sadly confused order" and how he carried on, layer by layer, dissections of the muscles, vessels, nerves, bones. Such skill with the knife had not been seen before in the city on the Seine. He performed the "Public Anatomy" of that year (and the next) single-handed and alone, *solito absolutius*. It was the third he had ever seen.

Vesalius had returned to Louvain in July, 1536, and after spending a year there, during which he presented his translation of the IXth book of Rhazes as a thesis for his doctor's degree (February, 1537), we lose track of him for some three months. He is next heard of in Padua where in December, 1537, he had been made a professor of surgery, which involved the responsibility of giving a public dissection. This he did with consummate success, and according to contemporary accounts, students traveled from great distances to see his public demonstrations.

The Tabulae Sex

We now come face to face with what Charles Singer refers to as the crux of the Vesalian problem. In a newly published monograph, entitled *A Prelude to Modern Science*, Singer and Rabin offer a minute study of the circumstances surrounding the publication of Vesalius' initial work issued at Venice on April 1, 1538, scarcely four months after he had reached Padua. During the past four hundred years, the six anatomical tables have been studied by eminent anatomists and historians and many distinguished artists, and even to Singer and Rabin they remain to some extent enigmatic. To Singer, Vesalius "opens a new scene as with the quick rise of a curtain, for it is essentially and brilliantly modern—modern in

appearance, modern in outlook, modern in method, modern in its art and in its technique. And modern, too, in what it omits no less than what it includes. It is a startling apparition in the very midst of that imitative world of the revival of classical learning which still pervades its language. To appreciate at all the magnificence of the great adventure of the *Fabrica* we must know something of its starting point—the starting point being the six anatomical tables."

The first three of the tables depict the portal circulation, the venous circulation, and the arterial, and together they represent an unoriginal résumé of Galenic anatomy. The heavy hand of tradition still lay upon the twenty-three-year-old Belgian anatomist. The vessels as delineated are inaccurate in many details, and they are more in line with the Galenic texts than with human anatomy as we now know it. Yet, as Singer eloquently points out, there had been nothing like them in technique of woodcut execution or in their attempt to provide medical students as well as anatomists with a visual image of the Galenic corpus.

It is probable that Vesalius himself drafted the original sketches on which the first three tables were based. Tables IV, V, and VI, on the other hand, were the work of Vesalius' colleague from the Low Countries, Jan van Calcar, and this is explicitly stated in the introductory comment to the first table: "I have sent these drawings themselves to the press," Vesalius writes. "To them we have annexed others comprising three representations of my skeleton which I have set up to the gratification of the students, rendered from three standard aspects by the distinguished contemporary artist, John Stephen [van Calcar]." Singer adds that the skeleton in question had been put together in January, 1538, for a public dissection at Padua, and that it must have come from the body of a youth aged about eighteen as is evidenced by the state of the epiphyses and sutures.

In the preface of the *Tabulae,* Vesalius mentions that he had a larger work in mind, and elsewhere (*Venesection Epistle,* 1539) he mentions that if he continues to have the services of his friend, John Stephen, he will get on with the work; but in 1543, when the great muscle plates of the *Fabrica* were to see the light of day, no mention is made of Calcar nor of any other artist who may have been associated with the undertaking. Singer and Rabin, without discussing the evidence pro and con, state categorically that it seems to them unlikely that any high proportion of the figures of the *Fabrica,* or the *Epitome* which also appeared in 1543, is by Calcar. As a working hypothesis they suggest that the artist of the *Fabrica* must have been "a young man, unknown to fame, who died before the book was printed." They add further: "It does not seem that they [the three skeletons of the *Tabulae*] are by the same hand that drew the three magnificent skeletons of the *Fabrica.* The jaunty gait of the fifth and the stiff lecture-room stance of the fourth are in strong contrast to the noble poses of the *Fabrica* skeletons. Nor does it need much anatomical analysis to see that many elements in the *Tabulae* skeletons are out of drawing. These conclusions seem to rule out the artist of the *Tabulae* as the artist of the *Fabrica.* When the *Tabulae* were published, Calcar was 39, an age that cannot be called formative for a draughtsman. It is difficult to believe that one who could work no better in line could develop at 44 into the great creative artist of the *Fabrica.* For this reason, among others, we do not believe that Calcar made most of the drawings for the later work."

The Singer-Rabin conclusions coincide with the general feeling of many scholars, but they are set forth in a dogmatic fashion and in the midst of a monograph heavily documented in other directions, but without the slightest indication of the basis of their sweeping deductions, beyond those actually stated in the quoted passages just given. Mr. William M. Ivins, Jr., formerly Curator of Prints at the Metropolitan Art Museum in New York City, has reached quite a different conclusion, namely, "that perhaps the more mature John Stephen, who paid the costs of printing and publishing the *Tabulae Sex,* was the real entrepreneur of the *Fabrica* and the *Epitome,* and that Vesalius' part . . . was merely that of a young medical man who was handy with his pen and who was engaged to write the commentary to accompany the drawings that John Stephen had made out of his long years of industrious investigation."[3]

This observation is challenging, for if Calcar, unaided, executed the plates and merely employed Vesalius as a hack writer, then the wandering artist of the Low Countries, who had had no formal training either in medicine or in dissection, must be proclaimed the founder of modern anatomy and experimental medicine.

Since the beginning of printing with movable

type, it has been customary for authors who wished to illustrate their books to seek professional assistance of draughtsmen, artists, woodcutters, engravers, and, more recently, of photographers. Anyone who has published a highly illustrated book in which the figures are drawn by an artist under the direction of the author fully realizes his debt to the artist, and there are many instances in which the excellence of the illustrative matter has been in large measure responsible for any success that the book enjoyed. The late Dr. Howard Kelly's monograph on the appendix and his textbook of operative gynecology have become collectors' pieces because of Max Brödel's remarkable drawings; but one could not claim that Brödel was the real entrepreneur of this classic. Similarly, in the eighteenth century William Hunter issued a memorable folio on the *Gravid Uterus*. The text, in this instance, was brief, but five or six of the best artists and engravers of the time were employed for the illustrations, and Hunter also had the wit to choose Baskerville as his printer, even as Vesalius had chosen his friend Oporinus. The Hunter plates have been profoundly admired, but here again the anatomist, not the artists, must be given primary credit for the princely folio.

Acknowledgment of indebtedness is usually made by the author to the artist and the engraver, but less frequently to the draughtsman who has been employed to make a linecut or diagram. In the fifteenth and sixteenth centuries it was not customary for an artist or an engraver to sign his illustrations, any more than it was common practice in the fifteenth century for a book to have a title page. Consequently, many of the finest early examples of the woodcutters', and later of the engravers', art have come down to us without indication of who executed them. If one examined illustrated works contemporary with the *Fabrica*, one would often find no indication of artist or engraver. It would thus appear that we can dismiss any deliberate attempt on the part of Vesalius to withhold credit from those who had assisted him.

In the second place it seems clear that it was Vesalius who first conceived the plan of preparing a human anatomy, and that he must therefore be allowed credit, not only for the originality of the idea, but also for his persistence in seeing the plan through. When we come to the *Fabrica*, the evidence of Calcar's participation, as Singer has implied, is less well established. Cushing, in a detailed discussion of Vesalius and Calcar in the introduction to his "Bio-bibliography,"[1] points out that in the *Venesection Epistle*, published somewhat over a year after the *Tabulae Sex*, Vesalius speaks in the preface of continuing his systematic studies and writes specifically: "We have now completed two plates of the nerves also: in the first the seven pairs of the brain are delineated; in the second the branches of the entire spinal cord are portrayed. I thought I ought to keep them till the time when I should undertake the plates of the muscles and all the inward parts. We have tried to make out a scheme of the dissections of this present year in the most convenient manner possible; but in view of the great crowd of spectators it proved altogether impossible to complete it."

There can be no doubt, however, that Calcar and his associates in Titian's studio did help materially with the drawings of the *Fabrica* as well as with those of the *Tabulae Sex*. The well-known collection of drawings originally belonging to Richard Mead, and transferred after his death to the Hunterian Museum at Glasgow, are almost certainly preliminary sketches made by Calcar for the *Fabrica*. That they were only preliminary is emphasized by Garrison[2] who draws attention to the fact that their outlines are obscure and much less accurate than those which eventually appeared in 1543. Indeed, they are precisely the type of preliminary sketch that any medical artist of the present day would submit to an author for correction and suggestion. The engraving of the bladder, for example, omits the openings of the ureters; these were subsequently introduced in the otherwise almost identical figure of the bladder which appeared in the *Fabrica*—an artist drawing such a lowly viscus could easily overlook these inconspicuous but physiologically important apertures.

But there is another and much more cogent reason for giving Vesalius primary credit, and that lies in the frontispiece of the *Fabrica* itself. Study of the preliminary *croquis* of the title page indicates that when the elaborate title was first drafted, and throughout the later stages of its development, there were two prominent figures, one, the central figure of Vesalius and the other the artist, notebook in hand, standing over Vesalius' shoulder sketching. The notebook, moreover, carries on its two covers the initials "S.C." [Steph-

en Calcar]. The earliest of the *croquis,* that at Stockholm, has the name "Jean Calkar 1675" written by a later hand. The Glasgow *croquis* was declared by Roth to be unquestionably the work of Calcar, and the important Crummer *croquis* is signed by the author in ink identical with that used for the drawing itself, *i.e., "Joh. Stephanus, inv. 1540 Venetiis."* The evidence that Calcar was responsible for the frontispiece is thus abundantly clear. If he had been the driving force responsible for the original dissections and Vesalius merely his convenient hack, would he have been so self-effacing as to place his ghost writer in the central position and himself in the background with his notebook? Since Calcar died two years after the appearance of the *Fabrica,* Vesalius, had he chosen to do so, could easily have blamed his artist for some of the errors that had to be corrected in the second edition. This he did not do in spite of the storm of abuse which the publication of his book had brought down on him.

One cannot leave the question of the authorship of the plates without considering Calcar's master. It has always seemed odd that Vesalius' contemporaries referred to the plates in the *Fabrica,* particularly those of the muscle men with the elaborate landscape in the background, as being the work of Titian, and that little claim was made for Calcar until the nineteenth century. May it not be that there is some basis for the earlier attribution? As just mentioned, it is well recognized that Calcar collaborated with Vesalius in the preparation of the *Tabulae Sex,* issued in 1538. But the extent to which Calcar or any other artist was involved in the larger undertaking of 1543 has nowhere been made clear and any claims for credit have always been based more on surmise than on documentary proof.

Quite recently, Dr. Erica Tietze-Conrat has disclosed an important contemporary reference to Titian's association with Vesalius, hidden away in the obscure *Diceria* of Annibale Caro.[7] In discussing "La statua della Foia, ovvero di Santa Nafissa," he makes reference to "La notomia del Vecelli," which unquestionably refers to the *Fabrica* of Vesalius. Although there is some uncertainty about the date of Caro's *Diceria,* internal evidence suggests that the passage in question was written in 1539; a later passage suggests 1543. Either date would be possible since Vesalius' association with Titian's studio began in 1538 (or possibly even in 1537), and the preface to his *Venesection Epistle* of 1539 indicates that in that year he was already planning the plates of the *Fabrica.* Caro spent several months in Venice in 1540, during which time he became intimate with Titian whom he met through his host, the poet Domenico Venier.

It is thus clear that Caro was in personal touch with Titian at the time the Vesalian plates were being designed, and the fact that so close a contemporary attributed them to Titian makes necessary a reconsideration of the part which Titian may have played along with his pupil Calcar in designing the plates. Miss Tietze-Conrat's conclusions seem highly relevant, and since her paper is published under a somewhat misleading title and would not ordinarily come to the attention of medical historians, it has seemed desirable to quote her argument in full:

> Caro's attribution to Titian does not represent a later tradition based on quality and substituting, as is always the case, a greater name for a lesser whose memory has faded; here, as a matter of fact, is no tradition at all, but an almost contemporary piece of information. How does this compare with the more precise and thrice repeated report by Vasari [in which he claimed authorship for Calcar]? Since Caro's observation proves that the attribution to Titian goes back to the sixteenth century, Vasari's remarkable emphasis on Calcar may have been meant as an intentional correction of what he considered an error. My personal opinion, however, is that Vasari might have wanted to throw light on the share in the woodcuts of his usually underrated "amicissimo Calcar." As a matter of fact, had attention not been drawn to Vasari's testimony, nobody would have questioned the attribution to Titian, since the postures and the proportions of the figures, and the landscape in which the figures are placed, are entirely in his style. They are so to such an extent that we are tempted to imagine that Calcar, whose portraits are very close to Titian's, was likewise dependent on Titian in his other paintings, none of which are preserved. Caro's early attribution of the *Anatomy* to Titian might be interpreted as evidence of a special sort of division of labor. When Vesalius wanted the illustrations made, he may have got into touch with Titian's studio. The assistant chosen for the task was probably Calcar, who, using either large nudes by Titian or, more likely, studies of poses made by him, transformed them into clear outlines which under Vesalius's supervision he filled with anatomical details. The latter alternative seems more attractive, since we are unable to imagine how such large nudes by Titian, none of which exist, may have looked. Calcar made a similar use of Titian's landscape sketches. According to my hypothesis then, the artistic invention of the figures, the *idea,* in the terminology of the period, and the *mise en scène* would be Titian's, while Calcar's would be that of the "medical designer," "il che gli

doverà in tutti i tempi essere d'Honore." This would correspond exactly to the division of labor typical of Raphael's studio and such an amount of participation by a pupil would also be compatible with any reasonable conception of Titian's workshop. The painstaking rendering of the minute results of the anatomical studies would contradict any notion that Titian himself was the medical designer.

Dr. Tietze-Conrat's deductions appear fair and reasonable, and when considered in association with evidence from Vesalius' own writings, which have been fully set forth by Cushing in his *Bio-bibliography of Vesalius,*[1] one might permissibly reconstruct their relations as follows:

The young Vesalius appeared at Padua and Venice in the summer of 1537. In December he received not only his M.D. but an appointment to a specially created chair of surgery, in connection with which he was obliged to give public dissections. By January, 1538, or possibly earlier, he must have fallen in with artists in Titian's studio, for by April 1 they had between them designed and published the *Tabulae Sex.* Within a few months of the appearance of the six tables, they were planning the larger work, and if Miss Tietze-Conrat is correct, Titian was consulted and began to direct the planning of the figures.

But whatever their contentions concerning the authorship of the *Fabrica,* historians of medicine will heartily agree with Mr. Ivins[4] on one point—that the reason why the *Fabrica* marked a turning point in the history both of medicine and art lies in the fact that for the first time a satisfactory synthesis had been reached between the work of the artist and the verbal descriptions of the physician-dissector. It was an achievement made possible by highly effective collaboration, and the imaginative direction of the undertaking came from Vesalius, rather than from his artist associates, however skillful and talented they may have been in assisting with the master plan.

The impact of the young Vesalius on medicine has been felt for four centuries and more—and his life achievement will ever serve as a stimulus and inspiration to those who practice the art of medicine.

* * *

Since it is in libraries that we preserve the record of the contributions of such men as Vesalius, I should like in closing to express one additional thought about physicians and medical libraries.

There are more than 2,000 county medical societies included within the continental United States and the Territory of Hawaii. About 10 per cent, or some 200, have attempted to maintain medical libraries, and I think you will find that the societies which have the foresight to support their own library are the ones responsible for medical progress, for the one unmistakable hallmark of the intellectual vigor of any group lies in its library, and by it one can unfailingly judge the intellectual and scientific preëminence of the men who have founded and supported it. If a group has the urge to support an institution such as this, and to command personnel of the quality of Miss Mary Post and Mrs. Eleanor Olson, and of Miss Isabelle Anderson who has so recently left you after seventeen years of devoted service, it becomes automatically a great force for progress in the profession. On behalf of another medical library which is only seven years of age, I bring sincere congratulations to your older institution on its fiftieth birthday—and I must add that the Historical Library at Yale takes inspiration from your example.

A hospital would not think of failing to provide a patient with a routine urinalysis, and yet it is stated that only four-tenths of one per cent of cases of diabetes are discovered by such a routine procedure. The amount of significant tuberculosis discovered by providing a routine x-ray is much larger. It is also said that less than one per cent of patients provided a routine blood count have a blood dyscrasia. Less syphilis is found by providing routine Wassermanns than significant tuberculosis by providing a routine chest x-ray.—ALLEN FILEK, M.D., NTA Trans., 1947.

Preventive medicine requires not only the co-operation, consent, and understanding of the individual who is to be benefited; oftentimes he must take the initiative—he must realize that it is just as important to seek advice from his physician on how to keep well as it is to call upon the physician for help when illness strikes.—Medicine in the Changing Order, Rep. N. Y. Acad. Med. Comm., Commonwealth Fund, 1947.

THE ASSASSINATION AND GUNSHOT WOUND OF PRESIDENT ABRAHAM LINCOLN

OWEN W. PARKER, M.D.
Duluth, Minnesota

THE terribly tragic war between the states started by the firing on Fort Sumter in April, 1861, and ended when the brilliant, gallant, and noble Lee met the modest, silent, and imperturbable Grant under the apple tree at Appomattox, April 9, 1865. A report at that time stated "The whole country was clad in the garments of joy and every face wore an expression of gladness. The bells from Maine to California and from the Lakes to the Gulf pealed forth tones of exultation as better and still better news arrived." Great was the happiness and relief of the war-worn, sad-faced President. A crowd gathered before the White House and called for the President. A band serenaded, and then Lincoln appeared. He spoke a few words to the assembly and asked the band to play "Dixie."

General Grant came on to Washington and was the great hero of the day. The Cabinet met with President Lincoln. The city of Washington was surcharged with tenseness, joy and exultation, and withal much work. On Good Friday evening, April 14, 1865, Laura Keene, the great actress, was to appear at the Ford Theater in Washington in the play "Our American Cousin," a broad comedy. Mrs. Lincoln was desirous that the President and herself attend the theater with General and Mrs. Grant as their guests, but at the last moment General Grant had to go to New York and so Major Rathbone and his fiancée, Miss Clara Harris, accompanied the President and Mrs. Lincoln to the theater and occupied the State box with them.

The presidential party entered the box about 9:00 p.m. President Lincoln sat in a rocking chair near a door leading into the box through which the assassin entered. He was shot about 10:30 p.m. by John Wilkes Booth, a brother of the great actor and tragedian, Edwin Booth, and a handsome young actor himself, of whom it was said, "So bright, so gay, so kind, no young man had brighter prospects in life." The clearest account of what happened in the Ford Theater on this tragic night of April 14, 1865, that has come to my observation, is given by Dr. C. S. Taft, Assistant Surgeon, U. S. A., under the title "Last Hours of Abraham Lincoln," which I quote in full:

The following brief report of the circumstances attending the assassination, last hours, and autopsy of the late President, will doubtless prove of much interest to the profession, and may be relied upon as correct in all particulars, the notes from which it is written having been submitted to comparison with others taken, and corrected by the highest authority.

While sitting in an orchestra chair at Ford's Theatre, on Friday evening, the 14th inst., about 10:30 p.m., I heard the sharp report of a pistol in the direction of the State box, and turning my head in that direction, saw a wild looking man jump from the box to the stage, heard him shout *"Sic semper tyrannis"* as he brandished a glittering knife in his right hand for an instant, and dart across the stage from sight.

A few moments of utterly indescribable confusion followed, amid which I heard a call for a surgeon. I leaped upon the stage, and was instantly lifted by a dozen pairs of hands up to the President's box, a distance of twelve feet from the stage.

When I entered the box, the President was lying upon the floor, surrounded by his wailing wife and several gentlemen who had entered from the dress-circle. The respiration was inaudible and scarcely perceptible, and he was totally insensible. Ass't Surgeon Charles A. Leale, U.S.A., was in the box, and had caused the coat and vest to be cut off, in searching for the wound. The wound in the head was soon found, but at that time there was no oozing from it.

Several gentleman in the box were insisting upon having the President removed to his home, but Dr. Leale and myself protested against such a proceeding, and insisted upon his being carried to the nearest house. He was removed to a house opposite, and laid upon a bed in fifteen minutes from the time the shot was fired.

The wound was there examined, the finger being used as a probe, and the ball found to have passed beyond the reach of the finger into the brain. I put a teaspoonful of diluted brandy between the lips, which was swallowed with much difficulty; a half-teaspoonful, administered ten minutes afterward, was retained in the throat, without any effort being made to swallow it. The respiration now became labored; pulse 44, feeble, eyes entirely closed, the left pupil much contracted, the right widely dilated; total insensibility to light in both.

Surgeon-General Barnes and Robert K. Stone, M.D., the family physician, arrived and took charge of the case. At their suggestion, I administered a few drops of brandy to determine whether it could be swallowed, but as it was not, no further attempt was made. The

left upper eyelid was swollen and dark from effused blood; this was observed a few minutes after his removal from the theatre. About thirty minutes after he was placed upon the bed, discoloration from effusion began in the internal canthus of the right eye, which became rapidly discolored and swollen with great protrusion of the eye.

About 11:30 p.m., twitching of the facial muscles of the left side set in and continued some fifteen or twenty minutes, and the mouth was drawn slightly to the same side. Sinapisms over the entire anterior surface of the body were ordered, together with artificial heat to the extremities.

The wound began to ooze very soon after the patient was placed upon the bed, and continued to discharge blood and brain tissue until 5:30 a.m., when it ceased entirely; the head, in the meantime, being supported in such a position as to facilitate the discharge. The only surgical aid that could be rendered, consisted in maintaining the head in such a position as to facilitate the discharge of the wound, and in keeping the orifice free from coagulum.

Col. Crane, Surgeon, U.S.A., had charge of the head during a great part of the time, being relieved at intervals in this duty by myself. While the wound was discharging freely, the respiration was easy; but the moment the discharge was arrested for any cause, it became at once labored.

It was also remarkable to observe the great difference in the character of the pulse whenever the orifice of the wound was freed from coagulum, and discharged freely; thus relieving, in a measure, the compression. This fact will account for the fluctuations in the pulse, as given in the subjoined notes.

About 2 a.m. an ordinary silver probe was introduced into the wound by the Surgeon General. It met an obstruction about three inches from the external orifice, which was decided to be the plug of bone driven in from the skull and lodged in the track of the ball. The probe passed by this obstruction, but was too short to follow the track the whole length. A long Nelaton probe was then procured and passed into the track of the wound for a distance of two inches beyond the plug of bone, when the ball was distinctly felt; passing beyond this, the fragments of the orbital plate of the left orbit were felt. The ball made no mark upon the porcelain tip, and was afterwards found to be of exceedingly hard lead.

Some difference of opinion existed as to the exact position of the ball, but the autopsy confirmed the correctness of the diagnosis upon first exploration. No further attempt was made to explore the wound.

After the cessation of the bleeding from the wound, the respiration was stertorous up to the last breath, which was drawn at twenty-one minutes and fifty-five seconds past seven; the heart did not cease to beat until twenty-two minutes and ten seconds past seven. My hand was upon the heart, and my eye on the watch of the Surgeon-General, who was standing by my side, with his finger on the carotid.

The decubitus during the whole time was dorsal, and the position on the bed diagonal; the length of the bedstead not admitting of any other position.

The respiration during the last thirty minutes was characterized by occasional intermissions; no respiration being made for nearly a minute, but by a convulsive effort air would gain admission to the lungs, when regular, though stertorous, respiration would go on for some seconds, to be followed by another period of perfect repose.

At these times the death-like stillness and suspense were thrilling. The Cabinet ministers, and others surrounding the death-bed, watching, with suspended breath, the last feeble inspiration, and as the unbroken quiet would seem to prove that life had fled, turn their eyes to their watches; then as the struggling life within would force another fluttering respiration, heave deep sighs of relief, and fix their eyes once more upon the face of their dying chief.

The wonderful vitality exhibited by the late President, was one of the most interesting and remarkable circumstances connected with the case. It was the opinion of the surgeons in charge, that most patients would have died in two hours from the reception of such an injury, yet Mr. Lincoln lived from 10:30 p.m. until 7:22 a.m.

The following observations of the pulse and respiration were noted down by Dr. A. F. A. King, at the bed-side, and are correct. The pulse was counted by Acting Ass't Surgeon Ford.

10:55—48. 11:06—45. 11:18—42, and weaker. 11:24—42, respirations, 27 per minute, breathing quiet. 11:26—irregular, intermits occasionally. 11:30—45, resp. more frequent and vigorous. 11:32—45, stronger, resp. much more strong and stertorous. 11:37—48, resp. again silent and more feeble. 11:40—45. 11:43—45, resp. stertorous. 11:47—45, resp. 24, stertorous. 11:56—48, weaker. 12:10—48, irregularly intermittent. 12:18—48, same character. 12:27—54. 12:28—60. 12:29—66, intermittent. 12:38—66. 12:45—69, intermittent. 12:49—84, resp. 28. 12:56—66. 1:00—100. 1:15—92. 1:30—95. 2:10—60, resp. 34. 2:19—58. 2:32—54. 2:37—48. 2:54—48, much weaker, more thready, respirations feeble. 4:18—60, resp. 27, strong and stertorous. 5:40—64, thready, resp. 27. 6:10—60, hardly perceptible (Barnes), resp. 26, stertorous. 6:25—thready, not counted; resp. 22; inspirations jerking. 6:40—inspirations short and feeble; expirations prolonged and groaning; a deep, softly sonorous, cooing sound at the end of each expiration, audible to bystanders. 6:45—respiration uneasy, choking and grunting; lower jaw relaxed; mouth open; a minute without a breath; face getting dark. 6:59—breathes again a little more at intervals; another long pause. 7:00—still breathing at long pauses. 7:20—died.

About 1:00 a.m., spasmodic contractions of the muscles came on, causing pronation of the forearms; the pectoral muscles seemed to be fixed, the breath was held during the spasm, and a sudden and forcible expiration immediately succeeded it.

At about the same time both pupils became widely dilated, and remained so until death.

During the night Drs. Hall, May, Liebermann, and nearly all the leading men of the profession in the city, tendered their services

Autopsy; Five Hours After Death

Present: Surgeon-General Barnes, Col. Crane, Dr. Stone, Ass't Surg. Woodward, U.S.A., Ass't Surg. Curtis, U.S.A., Ass't Surg. Notson, U.S.A., and Act'g Ass't Surg. Taft, U.S.A.

The calvaria was removed, the brain exposed, and sliced down to the track of the ball, which was plainly indicated by a line of coagulated blood, extending from the external wound in the occipital bone, obliquely across from the left to right through the brain to the anterior lobe of the cerebrum, immediately behind the right orbit. The surface of the right hemisphere was covered with coagulated blood. After removing the brain from the cranium, the ball dropped from its lodgment in the anterior lobe. A small piece of the ball evidently cut off in its passage through the occipital bone, was previously taken out of the track of the ball, about four inches from the external wound. The hole made through the occipital bone was as cleanly cut as if done with a punch.

The point of entrance was one inch to the left of the longitudinal sinus, and opening into the lateral sinus. The ball was flattened, convex on both sides, and evidently moulded by hand in a Derringer pistol mold, as indicated by the ridged surface left by the nippers in clipping off the neck.

The orbital plates of both orbits were the seats of comminuted fracture, the fragments being forced inward, and the dura-mater covering them remaining uninjured. The double fracture was decided to have been caused by contre coup. The plug of bone driven in from the occipital bone, was found in the track of the ball, about three inches from the external wound, proving the correctness of the opinion advanced by the Surgeon-General and Dr. Stone as to its nature, at the exploration of the wound before death.

The ball and fragments, together with the fragments of the orbital plates and plug from the occipital bone, were placed in the possession of Dr. Stone, the family physician, who marked and delivered them, persuant to instructions, to the Secretary of State, who sealed them up with his private seal. The Nelaton probe used was also marked by me, and sealed up in like manner.

Present in the room at Lincoln's death were Mrs. Lincoln; their son, Robert Lincoln; many members of the Cabinet; the doctors, including Surgeon General Barnes and Dr. Taft of the Army, and Dr. Robert K. Stone, Lincoln's family physician; the Rev. Thomas Gurly; and generals of the Army. As Lincoln died, Stanton, the great Secretary of War, uttered these historic and prophetic words: "Now he belongs to the ages."

General Grant's train en route to New York was stopped at Philadelphia, and the General was notified of President Lincoln's assassination and ordered back to Washington.

Major Rathbone is said to have first noticed the assassin of President Lincoln and grappled with him, but he was cut and slashed by a knife or dagger that Booth was carrying, and Booth escaped. Booth left the stage waving the dagger and shouting, *"Sic semper tyrannis"* (so be it always to tyrants) which appears on the seal of the State of Virginia.

Someone, comparing Lincoln to Duncan in Shakespeare's tragedy, quoted these lines, substituting the word Lincoln for Duncan: "Lincoln is in his grave; after life's fitful fever he sleeps well. Treason has done his worst, not steel nor poison, malice domestic or foreign, nothing can touch him further. This Lincoln hath done, his faculties so meek, hath been so clear in his great office that his virtues will plead, like angel's trumpet tongue against the deep damnation of his taking off."

A tragic fate awaited the five who entered the Presidential box that night. The President was assassinated, Mary Todd Lincoln, the President's wife, was ever after unhappy and became mentally ill. John Wilkes Booth, the assassin, in jumping from the President's box to the stage, caught his spur in the American flag which draped the box, and fell, fracturing a bone in his leg. Later he was shot to death by a soldier, Peter Corbett, while attempting to escape from a burning barn near Port Tobacco, Virginia. Miss Clara Harris who accompanied Major Rathbone to the theater was later murdered by him. Major Rathbone himself became a raving maniac.

In present times, President Lincoln would have been taken promptly to a modern hospital in an easy-riding modern ambulance over smooth pavement, but the doctors then felt it would be dangerous to move him in a horse-drawn vehicle over cobblestones, and so decided to carry him across the street to a small modest home, which they did, taking about fifteen minutes to get him into bed. In spite of modern means of transporting the injured, and the wonderful progress in brain surgery and medical treatment of brain injuries, I think it is the opinion of most surgeons who have studied the gunshot wound of President Lincoln, as shown by the recorded findings of the surgeons and the postmortem report of injury to the base of the brain and region of the pons, that the treatment today would be supportive and expectant observation. The subdural clots of blood might have been removed by surgery, but the

RECURRENT DISLOCATIONS OF THE SHOULDER

Experiences with the Transplantation of the Subscapularis Tendon

EDWARD H. JUERS, M.D., F.A.C.S.

Red Wing, Minnesota

THE treatment of recurrent dislocations of the shoulder is a perplexing problem. There is a note of encouragement, however, if one carefully studies the evolution of the operative procedures which have been developed since the turn of the century. It has been estimated that somewhat over sixty operative procedures have been described for the correction of this malady. Every operation which has been devised is based upon the use of one or more of the following principles: (1) reconstruction,[1,2,6,16,26] (2) supportive grafts,[3,4,7,9,10,11,13,23,26] (3 tendon transplants,[4,12,14,17,18,19,22,24,25,26] (4) muscle transplants.[5] The author's choice for the correction of recurrent dislocations of the shoulder is based upon the principles described by Magnuson and Stack.[18] Its merits will serve as the basis for this presentation. The operative technique, the postoperative management, and the reasons for choosing this procedure are set forth in the paragraphs to follow.

Operative Technique

The entire extremity and shoulder are surgically prepared in the usual manner. The former is covered with sterile stockinette and this is secured to the drapes so as to allow complete freedom of motion of the entire extremity without interfering with the remainder of the drapes. An anterior approach is utilized by making an incision 3.5 to 4 inches long, parallel to and over the bicipital groove. The delto-pectoral groove is identified to make certain of the location of the cephalic vein in order to avoid injuring it. The deltoid fibers are then separated by blunt dissection, starting at a point about 1 to 1.5 inches lateral to the delto-pectoral groove. The dissection is carried down to the rotator cuff. The subdeltoid fascia is retracted. Extreme care should be exercised to avoid injury to the circumflex branches of the axillary nerve which supply the anterior portion of the deltoid.

After the rotator cuff has been well exposed, the arm is rotated externally, and the inferior margin and also the width of the attachment of the subscapularis tendon are identified. The bicipital groove is located, for this serves as a future landmark (Figs. 1, a and b). With the arm

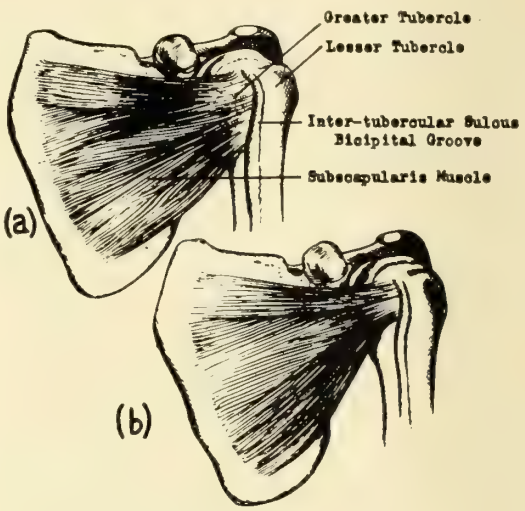

Fig. 1. Insertion of subscapularis tendon, (a) with wide attachment, (b) with narrow attachment. Identifying landmarks are also shown.

in external rotation, a small, slightly curved, periosteal elevator or a curved hemostat is introduced beneath the subscapularis tendon and directed upwards and parallel to the shaft of the humerus (Fig. 2a). The point of this instrument is brought out through an opening in the tendon or the rotator cuff (for narrow attachment). The tendon is incised down to the periosteum at the most distal part of its insertion (Fig. 2a). This incision starts at the level where the instrument protrudes through the opening in the tendon or rotator cuff and extends down as far as the inferior margin of the tendon. The insertion of the tendon, with its osseous attachments, is separated by means of a gouge. If the tendon is of an average width, approximately three-fourths is separated (Fig. 3). If it is quite narrow, the entire insertion should be detached (Fig. 2b). The detached portion is mobilized by cutting the fibers in the parallel axis for a distance of 1.5 to 2 inches (Fig. 3). At this point it is well to insert two traction sutures (Figs. 2b and 3) through the

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1947.

severed tendon in order to prevent retraction when the arm is internally rotated during the next step of the operation.

into the substance of the joint capsule along its antero-inferior margin. This suture is tagged and used later (Figs. 2b and 3). Two small drill

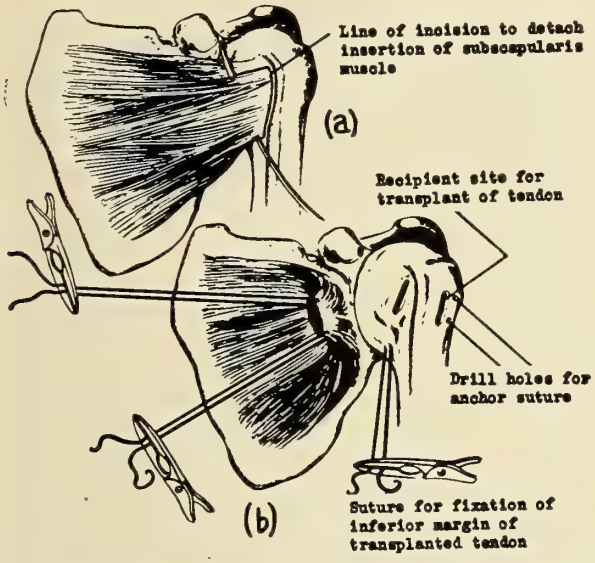

Fig. 2. (a) Elevator introduced beneath supscapularis tendon of average width. (b) with a narrow attachment, the entire insertion is detached.

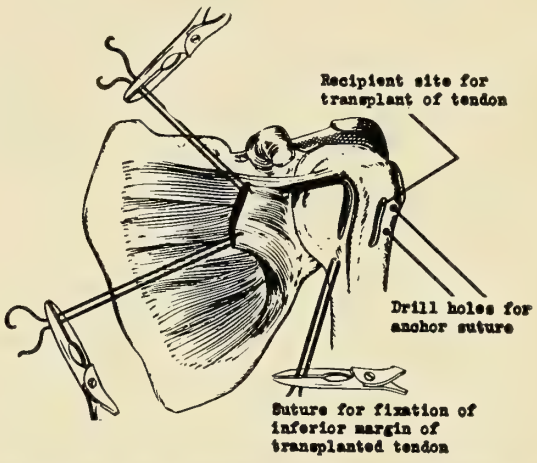

Fig. 3. With an average or wide attachment, about three-fourths of the tendon insertion is separated.

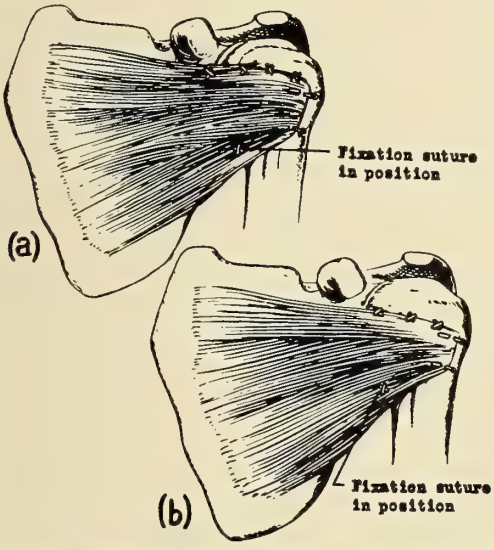

Fig. 4. Appearance of the transplant when completed, (a) with a wide tendon attachment, (b) with a narrow attachment.

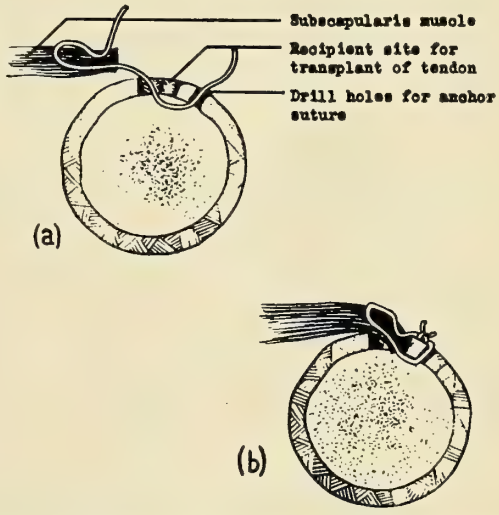

Fig. 5. (a) Placing of anchor suture. (b) Anchor suture completed.

In the next step, a portion of the cortex of the humerus is removed at a point lateral to the bicipital groove and at a level slightly lower and more distal than that of the original attachment (Figs. 2b and 3). This is the recipient site and should be about one centimeter more distal or lower on the shaft of the humerus than the donor site. At this time it is well to anchor one suture

holes are made through the cortex of the humerus, lateral to and communicating with the recipient site (Figs. 2b, 3 and 5a). Individual sutures of double strand chromic catgut are passed through each of the drill holes (Fig. 5a). These two sutures are used as anchor sutures for the tendon when it is transplanted. After the transplant has been completed, the upper edges of the cut ten-

don are firmly sutured to the rotator cuff by means of interrupted sutures of catgut (Fig. 4, a and b). The suture which was previously tagged is now brought through the substance of the inferior margin of the transplanted tendon and securely tied (Fig. 4, a and b). This serves to increase the sling effect of the transplanted tendon.[18] The incision is closed in the usual manner. The extremity is immobilized by means of a sling, adequately secured to prevent abduction and external rotation.

Postoperative Management

The patient is allowed out of bed as soon as he has recovered from the effects of the anesthetic. The arm is kept immobilized in a sling adequately secured to prevent abduction and external rotation. This immobilization is continued for a period of four weeks. Following this, active motion, muscle development of the rotator cuff, especially the internal rotator group, and physiotherapy, in the form of heat and massage, is instituted. At the end of six to eight weeks most patients are able to abduct the arm to 90 degrees and have recovered approximately 75 per cent of their external rotation. *Forceful* abduction and external rotation are not encouraged beyond the point of discomfort until a period of four months has passed.

Preferential Reasons

1. This is a surgical approach which is not encumbered by vital structures.

2. No secondary incisions are necessary to obtain supportive grafts of bone, fascia, or tendon.

3. There are no complications or disability such as occasionally result at the donor site following the removal of fascia lata, bone, or tendon.

4. The operation is based on sound physiological and mechanical principles. The sling formed by the transplanted tendon makes an excellent support to maintain the head of the humerus in the glenoid and at the same time interferes very little, if at all, with the function of the subscapularis muscle.

Thirty-four patients were treated by this operative procedure. A complete and satisfactory follow-up is not available because many of them were operated upon at Guam. Of those who were carefully followed for periods ranging from fifteen to eighteen months, the results were excellent. Several additional patients were heard from six months after surgery but these had not as yet regained a full range of motion.

Discussion

In view of the fact that primary dislocations often produce a traumatic functional disability of the subscapularis muscle[20] as well as stub fractures,[20] avulsion of the glenoid labrum,[1,2,20] and a posttraumatic bursitis beneath the inferior margin of the rotator cuff,[20] it is not difficult to visualize why transplantation of the subscapularis tendon is effective in producing a cure in cases where the dislocation has become habitual.[17,18] A simple capsulorrhaphy[16] in the presence of a wide tendon, no doubt, will produce a fair percentage of good end results. Surgical trauma[26] of a sufficient degree to cause formation of adequate scar tissue which is capable of setting up a barrier for the gliding humeral head is in itself effective in a small number of cases. The operation in which a bone peg,[3,7,23] is inserted into the anteroinferior margin of the glenoid is designed to work on the barrier principle. It is also conceivable that the Bankart operation[1,2] and modifications[6] thereof achieve some of the good end results from the same principle. The suspension operations[4,5,9,10,11,12,14,19,22] are not based on this idea and therefore depend entirely upon the support given by the transferred tendon or fascia.

It is my opinion that dislocations which occur following any corrective operative procedure for recurrent dislocation of the shoulder can be largely attributed to improper postoperative management. I have had occasion to observe a number of such incidents, and in every instance the surgeon's enthusiasm failed to take into account the slow rate of nature's reparative processes. In every case, activity was forced or encouraged so that the patient would have a considerable range of motion at the end of three weeks following operation.

I believe it is imperative that adequate immobilization should be instituted and maintained throughout a period sufficiently long to allow nature's healing processes to achieve a desired maximum. This should be followed by physiotherapy designed to re-establish the muscle co-ordination of the rotator cuff. Special attention should be directed to rehabilitate the power of internal rotation. Power for this motion can be achieved by

(Continued on Page 160)

THE SURGICAL TREATMENT OF ANEURYSM OF THE ABDOMINAL AORTA

CHARLES E. REA, M.D.
Saint Paul, Minnesota

THE following case of aneurysm of the abdominal aorta is reported because of (1) the long history before treatment was instituted, (2) the long survival after first operative treatment, and (3) the two different surgical approaches to treatment.

Comprehensive reviews of the subject of aneurysms of the abdominal aorta have been given by Matas, Bigger, Elkin, and DeTakats and Reynolds. Suffice it to say, that over 500 cases have been reported in the literature, of which thirty have had surgical treatment. From Bigger's statistics, about 80 per cent of patients suffering from abdominal aneurysms die in less than one year after onset of symptoms* DeTakats, in a review of the literature, found instances of only six patients who survived operation for more than one year; to this series he added two cases of his own.

The operative treatment of aneurysm of the abdominal aorta consists of wiring, coagulation, the application of the Matas principle of endoaneurysmorrhaphy or ligation by means of fascia lata strips, metal bands, cotton tapes or cellophane. It is to be remembered that except for excision of the aneurysm any other treatment is palliative. To date there has not been a successful excision of a true aortic aneurysm, chiefly because of the failure of a collateral circulation to develop. This is in contradistinction to an arteriovenous fistula or coarctation of the aorta in which a good collateral circulation is usually present. Partial occlusion with metal bands or with silk or wire is usually unsuccessful because of the danger of rupture of the vessel at the point of ligation. Bands of fascia or tape frequently give way and allow the channel to reopen.

From the experimental work of Page and Pearce, the use of a cellophane wrap to produce a gradual fibrotic compression of the aorta was suggested. In 1939, Page wrapped the kidneys of dogs in cellophane to produce hypertension. A marked tissue reaction was said to have occurred within three to five days following the application of "ordinary" cellophane. Within two weeks, a dense fibroblastic and collagenous deposit developed over the surface of the kidney, forming a constricting hull from 3 to 5 mm. in thickness. The hull continued to thicken for an undetermined period of time despite the disappearance of the cellophane. A foreign body reaction was said to have been produced by all of the varieties of cellophane used, although the moisture-proof types appeared less reliable than the others.

Harrison and Chandy wrapped cellophane proximally and distally to subclavian aneurysms in two Arabs. One of these was successful, the complete occlusion taking nineteen months. They suggested the use of this substance for the gradual occlusion in aneurysms of the aorta. DeTakats and Reynolds treated three cases of aneurysm of the abdominal aorta with eighty-ply cellophane; the patients were living up to fourteen months after operation.

Poppe and DeOliveira concluded from their experiments on dogs that Dupont 1.5 mil. polythene cellophane seemed to offer the most successful method of gradual fibrosis and obliteration of aneurysms and large vessels. The polythene cellophane which they used caused a pronounced fibrous reaction around the aorta in experimental animals. They used the same material on four humans, but without sufficiently long follow-up to report results. Osler Abbott has reported the use of polythene cellophane in the treatment of aneurysm of the thoracic aorta, its branches and of the pulmonary artery.

In direct contradistinction to the above work, other investigators consider cellophane as a physiologically inert substance. In 1936 Donati was the first to demonstrate this inert property of cellophane. Using regular commercial cellophane, 0.02 mm. in thickness to prevent adhesions between the brain and skull, he found the cellophane to be close to the brain after thirty-five days, with no irritative reaction surrounding it. McKeever studied the effect of cellophane (300 PUT and

Presented before the Saint Paul Surgical Society, October 15, 1947.

*This statement applies more to syphilitic aneurysm than to those on an arteriosclerotic basis. Dr. John Lepak, of Saint Paul, informs me that one of his patients had an arteriosclerotic aneurysm of the abdominal aorta for thirty-five years, the walls of which later became calcified. Dr. C. N. Hensel, of St. Paul, has had a patient who survived at least twelve years after the diagnosis of arteriosclerotic aneurysm of the abdominal aneurysm was made. The fact that patients with arteriosclerotic aneurysm may survive a long time without treatment should be taken into consideration in advising surgical therapy.

71) in the treatment of arthritis, and found no reaction caused by the cellophane for at least two months after operation. Similarly, Wheeldon, using 300 moisture-proof cellophane as the lining of the joint in arthroplasty, found no irritation of the tissues. Ingraham, Alexander and Matson state that animal experimentation with the synthetic plastic material, polyethylene, in the form of flexible tubing and film has shown it to be well tolerated in animal tissues when used in pure form. There is no foreign body reaction, the tissue response being similar to that seen in the use of tantalum and methyl methacrylate. These authors insist that the polythene be pure, for in their experiments on cats, in replacing the dura with polythene, the impure material caused hematomata which were gradually absorbed and replaced by scar tissue. Brown, Grindlay, and Craig found that polythene was inert and could be used in the reconstruction of common ducts, the trachea, colon, et cetera.

In considering the above divergent views it is apparent that varieties of cellophane act differently in causing tissue reaction and that the same type of cellophane acts differently, depending on whether it is in a pure or impure state. It may be questioned how much tissue reaction is nonspecific foreign body reaction dependent upon surgical trauma, sutures, et cetera, rather than due to cellophane. Also, the time element may be important. Cellophane which may cause no tissue reaction in short-term experiments may cause fibrosis over a long period of time. These questions await further experimental study.

It should be mentioned that the cellophane in this country is manufactured by E. I. duPont de Nemours and Company, Incorporated, of Wilmington, Delaware. Polythene in bulk is furnished to manufacturers by this company. According to Mr. C. L. Blair, of the Technical Service of the duPont Company, plasticizer or any anti-oxidant material is not used in their make of polythene. There is incorporated in their polythene sheets less than 1 per cent of an ester-like material as an essential item in the manufacturing process. The nature of this ingredient is considered confidential to their process and cannot be revealed. Mr. Blair kindly furnished the polythene used in this reported case, which is the same type of material supplied to Dr. J. Karl Poppe.

The circumstances under which such occlusion of the abdominal aorta may be considered justifiable are as follows: (1) the patient should not be a poor risk, (2) there should not be extensive diffuse calcification of the aorta, and (3) the aneurysm should arise from the aorta distal to the renal arteries.

The following case is of interest because the patient had had a palpable aneurysm of the abdominal aorta for eight years before surgical treatment and he was living four years after a fascial taping proximal to the aneurysm. When he was operated upon again, a cellophane wrapping was applied to the proximal end of the aneurysm and another "patch" applied to the superior anterior surface of the aneurysm. The patient survived five months, when he died of a coronary occlusion. An autopsy was obtained.

Case Report

Mr. M. W., aged fifty-six, was admitted to St. Joseph's Hospital, Saint Paul, Minnesota, on April 20, 1947. He gave the following history:

In 1930 he was under the care of Dr. C. S. Raadquist at Hibbing, Minnesota, because of indefinite abdominal distress, which cleared up with diet. Also, he had pain in the back of the neck, which ran up into the occipital region.

In 1932 he was again seen by Dr. Raadquist and Dr. C. N. Harris of the Adams Clinic, because of a burning sensation starting in the pit of the stomach and radiating to the chest over the sternum. It was also present in both shoulders and down the arms to the hands. Eating aggravated the sensation and milk made it worse. He complained of much bloating, and when gas did form, the pain was worse.

In 1935 he had a similar attack, and at this time a diagnosis of coronary disease was made. At this time there was a small mass in the abdomen in the midline, which was pulsating. Gastrointestinal study showed diverticula of the colon. The mass in the abdomen was 4 by 5 cm. in diameter. A diagnosis of aneurysm of the abdominal aorta was made, which was confirmed by Dr. E. L. Tuohy of the Duluth Clinic. Blood pressure at that time was 106/70. An electrocardiogram showed a recent coronary occlusion involving the posterior descending branch of the right coronary artery.

In November, 1942, he had a check-up at the Duluth Clinic because of another coronary attack. The abdominal mass at that time measured 9 by 12 cm.

On May 20, 1943, the patient was seen at the Mayo Clinic where he was operated upon by Dr. J. de J. Pemberton for aneurysm of the lower abdominal aorta. According to Dr. Pemberton, at operation the aneurysm was about 10-12 cm. in size and was situated behind the mesentery of the small bowel. It began just at the terminal end of the aorta before it divided into the common iliac. A piece of fascia, 0.75 inch thick, was taken from the right thigh and wrapped around the aorta twice, producing partial constriction of the aorta just proximal to the aneurysm. Dr. Pemberton estimated that the proce-

dure reduced the amount of blood through the aneurysm about 80 per cent. The patient left the Mayo Clinic June 9, 1943. The danger of rupture was explained and he was told to limit his activities.

In September, 1943, he was seen, at which time he had a pulsating mass 13 by 15 cm., the larger diameter being transverse. It showed 5 cm. above and 8 cm. below the umbilicus. Blood pressure was 112/68. He complained of epigastric distress, which was thought to be of coronary origin.

In October, 1944, he was again seen, when he complained of pain in the back. The mass in the abdomen was getting larger.

The patient was seen at the present admission in February, 1947. The patient complained of numbness and tingling of the toes. The mass in the abdomen also bothered him, and he wished something done, because he was "afraid that it might rupture." He was admitted to St. Joseph's Hospital April 4, 1947. Physical examination revealed a mass in the abdomen which measured 13 by 18 cm. It was situated below the umbilicus, was smooth, oblong, not tender to palpation. Blood pressure was 120/60. Examination of the blood and urine were essentially negative. Wassermann and Kline tests were negative. His heart showed left ventricular hypertrophy. The patient was operated upon on April 21, 1947, under cyclopropane anesthesia, through a right lower paramedian incision. The aneurysm was adherent to the anterior abdominal wall. The dissection was carried medially and the aneurysm was finally freed from the anterior abdominal wall. The retroperitoneal duodenum was lifted up and the root of the aorta visualized. There was no evidence at this time of the fascia lata strip. The aorta was atheromatous, especially on the anterior superior aspect of the aneurysm. Because of adhesions, the lower end of the aneurysm could not be definitely felt, but it certainly was down to the bifurcation of the aorta. A piece of polythene cellophane, 1 inch in width, was placed around the upper end of the aneurysm, and also another strip, about 2.5 by 3.5 inches, was placed over an atheromatous plaque on the anterior superior portion of the aneurysm. These were held in place by interrupted 0000 silk. The abdominal layers were closed with interrupted 000 silk. At the time of operation, a small piece of cellophane was placed subcutaneously, lateral to the incision in order to determine how much fibrosis might occur.†

The patient made an uneventful convalescence. He reported that the numbness and tingling of his toes had disappeared after operation and his feet felt warmer. It is a question whether the freeing of the aneurysm from the anterior abdominal wall had anything to do with it. The patient was discharged from the hospital on February 27, 1947. He was seen on June 11, 1947, at which time he felt well, the wound was well healed and the aneurysm measured 10 by 15 cm. Also, there seemed to be less pulsation in the aneurysm. The amount of fibrosis about the piece of cellophane placed subcutaneously and laterally to the incision was not remarkable at this time.

The patient wrote in July and August, 1947, that he felt well and was coming for a checkup, when, on September 16, 1947, he died suddenly from coronary occlusion. An autopsy was performed by Dr. G. Berdez, pathologist at St. Mary's Hospital, Duluth, Minnesota. The pertinent findings were as follows:

The heart weighed 530 grams. The cavities of the heart were markedly dilated, mainly the left ventricle, and there was an "aneurysm" of the lower half of the anterior wall of the left ventricle measuring 7 by 5 cm. and containing some mural thrombi. In that region the wall of the left ventricle was very much thinned out, formed by scar tissue, and measured down to .2 cm. in thickness. The cusps of the aortic valve were somewhat thickened and fibrous, and showed small areas of calcification. The other valves showed nothing of note. The foramen ovale was closed. The entrance to the coronary arteries was markedly narrowed. The coronary arteries showed arteriosclerotic changes, grade III, and were quite narrow. The anterior descending branch of the left coronary artery showed a marked calcification and was obliterated. The circumflex branch was almost obliterated and also showed some calcification. The right coronary artery was quite narrow. The aorta showed marked arteriosclerotic changes. There was a large aneurysm of the lower part of the abdominal aorta, just above the bifurcation. After filling this aneurysm with water, it measured 14 cm. in length, 10.5 cm. in width, and up to 8 cm. in thickness. Upon opening the aneurysm, the internal surface of the sac was somewhat irregular; large masses of thrombus material were attached to the internal surface. The wall of the sac (anterior wall) measured from .2 to .5 cm. in thickness and was quite fibrous; the wall was thickest in the upper anterior surface. The common iliac arteries, anterior to their bifurcation into the internal and external iliac arteries, showed also a marked and diffuse dilatation and measured up to 4 cm. in diameter; upon opening those vessels, there were masses of thrombus material which were still attached to their internal surface. The aorta showed marked arteriosclerotic changes which involved the arch of the aorta, the thoracic and the abdominal aorta; the changes were more marked in the lower part of the thoracic aorta and in the abdominal aorta. The intima showed numerous prominent yellowish patches, some of them breaking down; the edges of the defect were sometimes slightly undermined, and the degenerative changes extended to the media. The aneurysm of the lower abdominal aorta started about 1 cm. below the place where the renal arteries left the aorta; just above the renal arteries, the internal circumference of the aorta measured 5.5 cm. in length; the upper opening of the aneurysmal sac measured about 4.3 cm. in circumference. Between this upper opening of the aneurysmal sac and the place from where the renal arteries left the aorta, there was a segment measuring 1 cm. in length which was dilated also. Between that dilated segment and the upper opening of the sac, there was a ridge which was slightly prominent in the lumen of the aorta. At that place, the connective tissue surrounding the aorta was more fibrous. Rests of a cellophane band which had been placed around the neck of the aneurysm could not be recognized grossly.

†Unfortunately, this area was not studied at autopsy.

Anatomic diagnosis:

1. Coronary sclerosis, grade III
2. "Aneurysm" of the anterior wall of the left ventricle.
3. Arteriosclerosis, grade III, of the aorta with aneurysm of the abdominal aorta.
4. Congestion and emphysema of the lungs.

Comment

It is interesting that there was fibrous thickening at the upper end of the aortic aneurysm where the fascial strip and cellophane band had been placed. Also the wall of the sac seemed thickest in the upper anterior surface of the sac where the cellophane patch had been applied. No evidence of cellophane could be found on the aneurysm or in the peritoneal cavity at autopsy.

Because there had been a previous fascial taping at the neck of the aneurysm, it is impossible to say how much of the fibrosis was due to the fascial band and how much to the cellophane. However, it would seem logical to assume that the cellophane produced some fibrosis, at least on the anterior surface of the aneurysmal sac. For this reason, its use in the treatment of aneurysm would seem justified.

Summary

The case of an arteriosclerotic aneurysm of the abdominal aorta in a fifty-six-year-old male is presented. The patient had a palpable aneurysm for eight years before surgical treatment. He lived four years after a fascial taping proximal to the aneurysm and five months after placing a cellophane band at the neck of the aneurysmal sac and a cellophane patch over the anterior surface of the sac. The patient died of a coronary occlusion. At autopsy there was evidence of fibrosis caused by the cellophane.

THE ASSASSINATION AND GUNSHOT WOUND OF PRESIDENT ABRAHAM LINCOLN

(Continued from Page 149)

destruction at the base of the brain and the pons seemed too great for survival even with a successful operation for removal of blood clots. There can be no doubt that the wound was a fatal one and that modern scientific medicine and surgery could not have saved the great man and President.

Lincoln, perhaps more than any man of our nation, has become enshrined in the hearts of the people. When the Blue and the Gray met and shook hands at the Bloody Angle on Cemetery Ridge at the Gettysburg Battlefield fifty years after the Battle of Gettysburg, the Rev. Dwight Hillis who addressed them, speaking of Lincoln, said, "When God wanted a father for his bondmen, He went to the poor man's log cabin in Kentucky, and taking his babe in his arms, called the best loved angel of heaven and of earth, the angel of mercy, and said—take this child, plant his pathway thick with thorns, cut his feet on the jagged rocks of time, take from him everything that he loves, break his heart a thousand times, and when you have done, bring him to the throne, and I will make him *great*. Thus did the great God make Abraham Lincoln the greatest man of the Republic."

RETINITIS PIGMENTOSA

F. N. KNAPP, M.D.
Duluth, Minnesota

RETINITIS pigmentosa is a primary pigmentary degeneration of the retina. It is chronic in character. There is a slow progression of degeneration with a gradual loss of vision terminating in blindness.

There are two characteristic symptoms of the disease: (1) night blindness, (2) a gradual diminution in the size of the visual field. Early in childhood these patients complain of nyctalopia (night blindness). This is usually the first indication of a visual defect. With advancing years, there is a loss of the peripheral visual field until the patient has only central vision. Both of these conditions greatly handicap the individual. Other similar abiotrophic anomalies of the retina are choroideremia and gyrate atrophy. In this class of diseases the macula area is the last part of the retina to be destroyed. Some other hereditary retinal diseases are characterized by an involvement of the macula area very early in the disease, such as the Laurence-Moon-Biedl syndrome.

A great deal of work has been done on the hereditary aspect of retinitis pigmentosa and other abiotrophic diseases. Regardless of the diversity of opinion concerning the type of heredity, there is undoubtedly a strong hereditary tendency for these conditions to occur in families. In many studies at least one-half of the cases show a hereditary transmission. If an older child develops night blindness, other children surely are in danger of inheriting the same condition. A mother with primary degeneration of the retina may transmit the disease to her children.

There are three types of hereditary retinitis pigmentosa. First is the dominant hereditary type. This type is rare. In this type, the disease is transmitted through the female and affects the sexes equally. The affected patients inherit the disease from one parent and pass it on to half of the children. Usually retinitis pigmentosa develops late in life, between twenty-five and fifty years of age in the dominant type of heredity.

Second is the recessive type of inheritance. Most cases are of this type. The recessive trait is most often found in consanguinous marriages. The disease is more severe and appears earlier than in the other types of inheritance. The number of carriers in this type is twice the number of those developing symptoms of the disease. The avoidance of intermarriage is imperative. The children of a father with retinitis pigmentosa will all be carriers.

The third type is a sex-linked heredity, and this type is rare. In the sex-linked heredity, half of the sisters of a male with retinitis pigmentosa and all of the daughters will pass the trait to half of their male children.

The clinical fundus picture of retinitis pigmentosa is characterized by a decrease in the size of the retinal vessels and peculiar pigmentary formation. Following the degeneration of the retina, pigment migrates in clusters, usually around the retinal vessels, resembling bone corpuscles. The pigmentary epithelium of the retina is decolorized. The choroidal vessels are visible and the fundus becomes tessellated. At first, the spots are smaller and are seen mostly in the periphery of the retina. Gradually, the pigment corpuscles increase in size and number, and more and more of these appear towards the macula area. The retinal arteries are greatly reduced in size until the arteries are mere threadlike bands. A peculiar pale wax color is seen over the optic disk. This is due to a formation of glial tissue and not to atrophy of the nerve fibers.

Many patients with retinitis pigmentosa are highly myopic. Many other defects may be found in addition to the retinal degeneration, such as deafness, mutism, and oftentimes nystagmus. In the later stages, posterior polar cataracts develop due to the malnutrition of the retina. The essential pathologic process seems to be a progressive degeneration of the neural epithelium with an early destruction of the rods. The destruction of the rods results in the early symptom of night blindness. There is general destruction of the neural epithelium with the formation of glial tissue.

THE PRESENT STATUS OF THE RELATION OF CHOLESTEROL TO ARTERIOSCLEROSIS

E. R. HAYES, M.D.

Minneapolis, Minnesota

THE purpose of this paper will be to show in a general way the state of our knowledge as it relates to cholesterol metabolism and the development of atherosclerosis. It is hoped also that it will be possible to point out some of the deficiencies in our present knowledge of this important subject.

For several years it has been recognized that cholesterol is present in the atheromatous plaques of atherosclerosis. There has been no agreement as to the mechanism of entry of cholesterol into the intima of the arteries. The two most recent theories as to the mechanisms are those of Hueper[6] and Leary.[9] Hueper has suggested that the cholesterol enters into the subintimal tissues by simple imbibition as a result of a disturbance of the plasmatic colloidal equilibrium which holds it in solution. According to this theory, the cholesterol appears first as an extracellular material, which as an irritant produces fibrosis. The cholesterol is later taken up by phagocytic cells to form the so-called lipophages.

Leary has suggested, on the other hand, and has marshalled considerable evidence from experimental animals in support of his theory, that the cholesterol is esterfied in the parenchymal cells of the liver. He postulates that under conditions of overload the hepatic cells become unable to metabolize the material, presumably are damaged, and are phagocytosed by the Kupffer cells. The Kupffer cells, now lipophages, enter the blood sinuses of the liver, are carried through the lungs, and finally enter the systemic circulation.

Even if one adopts Leary's theory, at this point a question arises for which there is as yet no answer. Why do these phagocytic cells with their load of cholesterol show a predilection for certain blood vessels? Leary has attempted to answer this question by saying that young fibroblasts in young vessels are able to metabolize the cholesterol and clear it from the blood vessel walls, and, further, that certain blood vessels, those commonly the site of atherosclerosis, lose this fibroblastic metabolic activity in adult life.

This fibroblastic reaction may well be the mechanism of metabolizing the cholesterol deposited in the blood vessels during youth, but it does not indicate why one blood vessel will react in a way entirely different from another blood vessel of similar size and similar histological structure, nor why the blood vessels of one person will become sclerotic while those of another person will not.

It can only be concluded at this time that the pathogenesis of atherosclerosis is not yet understood.

While a great deal is yet unknown concerning the intermediary metabolism of cholesterol, certain basic facts are now well established. Cholesterol is an unsaturated monohydric alcohol, $C_{27}H_{25}OH$, which forms a series of esters with the common fatty acids. The substance is present in practically all mammalian cells. Numerous investigations have been undertaken to establish some viscus as the chief site of formation of cholesterol; however, the present thought is that the material is formed in the cells in which it is found or that it is ingested preformed. Cholesterol is closely related chemically to many of the plant sterols; yet it has been shown by Schoenheimer[10] that these plant sterols are not absorbed by the human. Cholesterol is excreted largely in the feces in the form of its reduction products, coprosterol and dihydrocholesterol. As early as 1920 Gamble and Blackfan[3] showed that the human infant excreted coprosterol in excess of its intake of cholesterol. This was taken to indicate that the human infant was capable of synthesizing cholesterol. More recent studies using tagged carbon have confirmed this early conclusion.

Numerous studies on the levels of cholesterol in the blood, in both health and disease, have been carried out. Reports have been at variance as to the blood levels in atherosclerosis. This discrepancy might in part be accounted for by the fact that the cholesterol levels found in whole blood, serum, and plasma differ significantly. It, therefore, becomes necessary to make all analyses on the same material. Whole blood gives the lowest

values, oxalated or citrated plasma next, and serum the highest values. Heparinized plasma gives values comparable to serum which may be as much as 15 to 20 per cent higher than those obtained using citrated or oxalated plasma. This has been explained by Gardner, Gainsborough, and Murray[4] as the result of the shrinkage of the red blood cells due to the oxalate and citrate with a resultant dilution of the plasma cholesterol. We have found that oxalating the serum after separation from the cellular elements of the blood does not change the cholesterol content as determined by the method of Sperry and Schoenheimer.[11] The reduction is not apparently a direct action of the oxalate on the cholesterol. The difference in values obtained on serum and plasma are greater than one would expect from the amount of dilution encountered from ordinary oxalate, which is usually about 6 to 8 per cent. It does not seem then that one can accept without reservations the dilution theory as the entire explanation of the differences found in plasma and serum values. Discrepancies should be viewed in the light of the methods used and the materials analyzed.

More recently, probably as the result of improved analytical methods, more investigators are reporting what they regard as significantly elevated serum cholesterol levels in patients with proven atherosclerosis. Among these are Davis, Stern and Lesnick,[1] Steiner and Domanski,[12] and more recently Herrmann.[5]

The very nature of atherosclerosis, with the difficulties of early diagnosis, makes the accumulation of data difficult except late in the disease. Thus rarely can one know for sure what was going on during the period of the formation of the atheromata. It is conceivable, as suggested by Leary,[7,8] that the end result of atherosclerosis represents repeated episodes of hypercholesterolemia over a period of years with perhaps relatively normal values in the intervals. Attention has been called by Huepper[6] to the fact that once free cholesterol is deposited in the intima of the blood vessels it is in a relatively inert form and would be expected to remain either permanently or for a long period of time.

In support of this concept of repeated intermittent accretions during periods of hypercholesterolemia is the previously cited work of Steiner and Domanski.[12] They found that, whereas the serum cholesterol levels in their normal controls were relatively constant over the two-year period of observation, the values in individual patients with coronary arteriosclerosis fluctuated widely during the period of study.

It is hardly necessary to call attention to the incidence of atherosclerosis in such conditions as diabetes and hyperthyroidism—conditions which are associated with hypercholesterolemia.

Faber[2] has recently published the results of analyses of the aorta in normal persons and in patients with coronary occlusion. He has correlated these with serum cholesterol levels in the same individuals. In the control group he found an increasing amount of cholesterol in the aorta with increasing age, which was not related to any increase in the serum levels. On the other hand, in the patients with coronary occlusion he found a number of younger individuals with an increase in the cholesterol content of the aorta well above that of a much older group. In this group with increased cholesterol content of the aorta there was an associated hypercholesterolemia in the nonhypertensive individuals, yet not in those with hypertension. It would seem then that two factors might be operative: one a metabolic factor which results in hypercholesterolemia and produces atherosclerosis, the other a tissue factor dependent on injury to the vessel, as for example from hypertension, with an increased tendency toward the deposition of cholesterol even in the absence of hypercholesterolemia.

It would seem, therefore, that evidence is accumulating which is suggestive, at least, that certain individuals possess an inherently defective mechanism for metabolizing cholesterol. These individuals may resemble the rabbit, a species which develops atherosclerosis quite uniformly if fed cholesterol. Conversely, other individuals may be more similar in this respect to the rat, in which cholesterol feeding does not produce atherosclerosis.

Studies have been undertaken to evaluate the response of various individuals, both normal and atherosclerotic, to varying loads of ingested cholesterol. It is too early yet to report on the results of these studies.

The discovery of certain lipotropic substances which will mobilize lipids from the liver, has suggested to us that these same substances might be effective in mobilizing cholesterol from atherosclerotic arteries, or, what is more likely, they might be effective in preventing the deposition of the lipoid in the vessels of those individuals who are

predisposed to hypercholesterolemia. We are not yet in the position to report upon our experiments along this line, but Herrmann[5] has recently reported upon the effects of decholesterizing agents, among which are some of these lipotropic substances. He has found what he regards as a significant effect from substances like choline, methionine, and inositol. More work is necessary along this line before any definite conclusions can be drawn.

Conclusions

1. Cholesterol would seem to be related etiologically to the development of atherosclerosis. The exact mechanism is not yet established.

2. It is suggested that certain individuals have an inherent defect in cholesterol metabolism which results in fluctuations in their serum cholesterol levels, probably related to dietary intake. It would seem that these individuals should be protected from overload by ingesting a diet low in cholesterol.

3. There is suggestive evidence that certain of the lipotropic substances may be effective in reducing the serum cholesterol levels in certain individuals with atherosclerosis; however, further work is necessary on this subject.

RECURRENT DISLOCATIONS OF THE SHOULDER

(Continued from Page 152)

a well-developed subscapularis muscle, and it is my belief that a well-functioning subscapularis muscle is the best insurance against recurrence of a habitual dislocation of the shoulder.

Summary

1. The basic principles for correction of recurrent dislocations of the shoulder are enumerated.

2. The operative technique utilizing the principle of a tendon transplant is described.

3. A plan for postoperative management is outlined. Emphasis is placed upon a period of adequate immobilization followed by a well-guided program of muscle rehabilitation.

THE FERGUS FALLS CANCER DETECTION CLINIC

W. L. BURNAP, M.D., M. G. FREDERICKS, M.D., C. H. MEAD, M.D., L. L. MERRIMAN, M.D., R. J. MOE, M.D., O. B. PATCH, M.D., and A. H. WELLS, M.D.
Duluth, Minnesota

The first Cancer Detection Clinic conducted by a Medical Society in Minnesota was held in Fergus Falls on December 13, 1947. It is the purpose of this paper to set forth the rules and regulations, the organization and the results of this experiment.

Rules and Regulations

Each rule of conduct was separately voted upon by the Park Region and District County Medical Society at a previous meeting. Those of basic importance concern the examinee, fee, examining physicians, extent of the examination, reports, follow-up time, place, lay aids, promotion, registration, and the responsible committee.

It was decided to invite all apparently healthy adults regardless of financial status without reference and any others especially sent to the Clinic by their physicians with a letter of introduction. There was to be no fee. All participants conducting the Clinic, both professional and lay, were to be on a voluntary nonpay basis. Primarily, because of the prospects of a greater local success, representatives of the specialties, dermatology, surgery, gynecology, internal medicine, and otolaryngology were to be invited in to be in charge of their particular sections of the examination. The expenses of the out-of-town specialists were to be paid up to $35.00 if requested. The local physicians were to assist in any part of the physical examination best suited to themselves. It was decided to hold the Clinic on a Saturday so that more of the local physicians could participate and a grade school could be taken over for the entire day.

A history and physical examination form prepared for cancer detection examination by the Kansas State Medical Society was adopted. This form permits a checking of symptoms by systems in the past history of the examinees by nurses. The physical findings have an anatomical arrangement which facilitates the recording of special fields of examination by the specialists. In addition, there is a summary of findings and recommendations at the end of the folded four (4) page record. Routine visualization of the cervix and rectal examination were considered essential. However, proctoscopic and laryngoscopic examinations were to be carried out only at the discrimination of the examiner. Biopsies, x-ray examinations and therapy were specifically excluded. No comment concerning the findings or recommendations were to be made to the examinee except that they were to call their family physician.

All completed reports were to be sent to the examinee's local physician. The examinees were to be sent a postal card reminding them to call their family physician concerning the results. A statistical review of the records were to be made by the Committee on Cancer of the State Medical Society.

This group was also asked to follow up case studies through the family physicians involved and summarize the entire experience.

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

The local nurses' organization, the Red Cross and their nurses' aides were to be depended upon for a great contribution of time and effort. Other local organizations including the American Legion and the American Cancer Society consented to help. The latter organization was asked to pay the expenses of the imported specialists and other incidental expenditures. The Red Cross organization served coffee and doughnuts throughout the day to all assistants.

Two large advertisements announcing the time, place, sponsorship, limitations to healthy adults, place of registration, et cetera, were to be published in the local newspaper. Pertinent news items using local names were to be published and the radio station was to contribute spot announcements of the clinic.

All examinees were to register by phone at the local Red Cross office or with their family physician at least one week preceding the clinic. The examinee's name and family physician were recorded and appointments were given the rgistrants. It was left up to the local committee of three physicians to carry out the rules set down by the society and decide any of the details which might arise.

Clinic Organization

One week before the established date of the clinic 400 examinees were registered. Tactics developed in the late war for physical examinations of large numbers of men and women were adopted. Two series of examination rooms were set up to accommodate the two sexes (see accompanying sketch).

All examinees were checked at the entrance to the large gymnasium to establish their appointment. They then entered orderly lines to receive their case record from six lay typists who filled in the name, address, phone number, nearest relative, and name of the family physician.

In Room 1 the positive findings in their past histories were checked by six nurses.

From here all examinees visited Room 2 for ear, eye, nose and throat examinations, carrying their record sheets with them. Laryngoscopic examinations were performed only when indicated. Three specialists aided by two recorders were necessary.

The examinees undressed in separate rooms (3 and 4) and the women were supplied with a loose dress or dressing gown and shoes, and the men with pants and shoes. Weights, blood pressures, and temperatures were recorded here by male and female assistants.

The women proceeded to the gynecology room (5) where five examining tables were lined up facing one wall with tables, pans of cresylone, towels, speculae, flash lights, et cetera. Four physicians, four nurses and three recorders were necessary. The breasts, abdomen, cervical and rectal examinations were performed and results and recommendations recorded. In Room 6 the skin and mouth were examined by the dermatologist

SKETCH OF ARRANGEMENT OF EXAMINING ROOMS IN THE SCHOOL

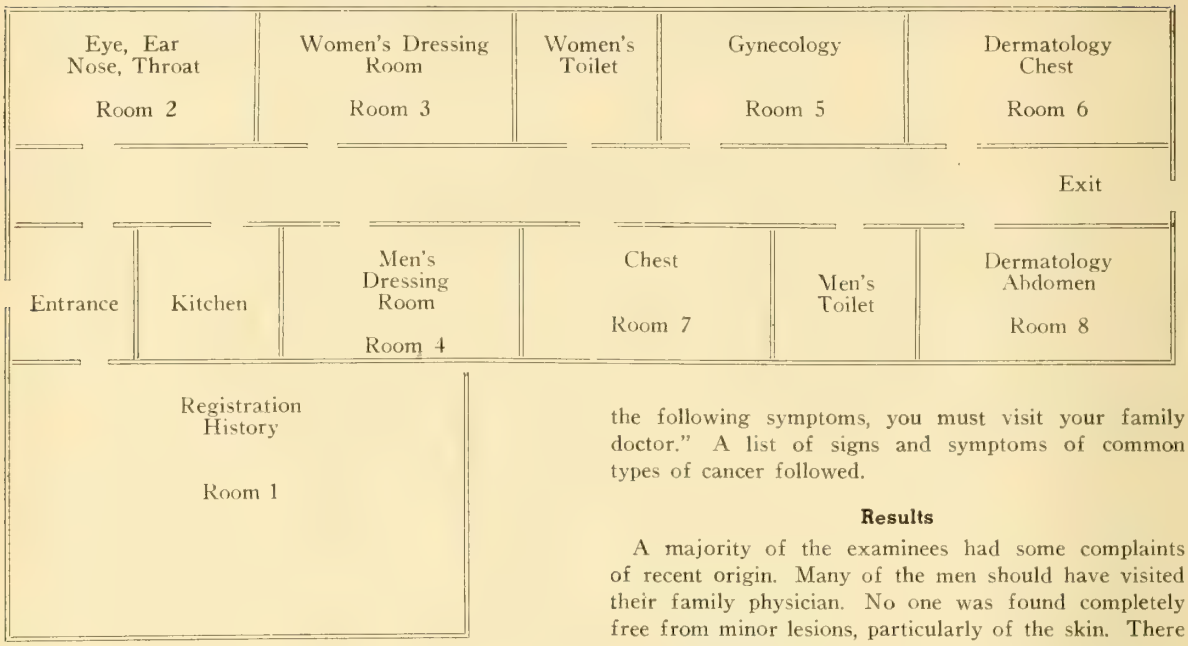

TABLE I. FREQUENCY OF SELECTED SUBJECTS IN THE PHYSICAL EXAMINATION, PAST HISTORY AND RECOMMENDATIONS

Physical Findings	*Women*	*Men*
Cervical ulcer, erosion, etc.	90-47%	....
Breast tumors	5-3	....
Moles	137-71	49-55%
Keratoses	40-20	11-12
Hemorrhoids	47-24	7-8
Murmurs	12-6	2-2
Hypertension	39-20	14-16
Prostatic hypertrophy	....	13-15
Other tumors	24-12	21-24
Other organic diseases	28-14	10-11
Some Items in Past History		
Headaches	63-33	21-24
Dizziness	53-27	22-24
Ringing in ears	30-15	4-5
Constipation	62-32	26-30
Other G.I. complaints	88-45	41-47
Evidence of peptic ulcer	....	8-9
Dyspnea	26-13	2-2
Recommended Diagnosis and Treatment		
Biopsy or cautery cervix	54-27	....
Dilatation and curettage of uterus	43-20	....
Skin biopsy and treatment	15-8	3-3
Skin surgery	46-24	5-6
Other biopsies	9-5	3-3
G.I. tract x-ray	16-8	18-20
Barium enema	7-4	11-12
Other laboratory procedures	10-8	22-24

and two physicians performed chest examinations on five examining tables. Three nurses and two recorders were used.

On the men's side there were two additional stops. In Room 7 chests were examined with the patient standing. In Room 8 abdominal, rectal and skin examinations were completed by three physicians with the aid of three nurses and two recorders.

After the examinations, all the examinees were given a card stating, "No examination will completely rule out the presence of hidden cancer. If you develop any of the following symptoms, you must visit your family doctor." A list of signs and symptoms of common types of cancer followed.

Results

A majority of the examinees had some complaints of recent origin. Many of the men should have visited their family physician. No one was found completely free from minor lesions, particularly of the skin. There were 191 women and 88 men examined between 9:00 a.m. and 6:00 p.m. Of the women, 125 (65 per cent) and of the men 64 (72 per cent) required treatment or further diagnostic study by their family physician. Selected subjects from the past histories, physical examinations and recommended procedures of diagnosis and treatment are best reviewed in table form (Table I). Scientific programs emphasizing early detection of cancer were presented to the local medical society and the laymen at separate meetings in the evening. Both were well received and proved to be an appropriate climax of the day.

Conclusions

Most of the physicians taking part in the examinations felt that they had experienced a momentous day, that the experiment was well worth the effort and that similar clinics could profitably be organized in other parts of the state. The local physicians were pleased with the results. A closer relationship between the laymen and physicians of Fergus Falls unquestionably exists as a result of the understanding co-operation in the clinic. The term "apparently healthy" adult does not define the patients attending this cancer detection clinic. The majority of the examinees had complaints of recent date, many had a history of cancer in the family and there was an unusually high percentage of disease processes found. To eliminate those with active symptoms from a clinic intended for "apparently healthy" adults some barrier must be set up at the time of registration. Disregarding the educational value of the clinic to both physicians and laymen and the services rendered to 279 people in Fergus Falls, we feel this experiment will reflect itself in cancer research. This will result in part through a stimulus to the many people throughout the state who are anxious for the physicians to show a more co-operative spirit in the present widespread movement to control cancer.

Case Report

TOXIC NEURORETINITIS

A. G. ATHENS, M.D.
Duluth, Minnesota

Mrs. J. C., a married woman, aged twenty-three, was referred by her family physician, Dr. H. Fisketti, on March 26, 1947, complaining of severe frontal headaches, shooting pains in the eyes and sudden loss of vision. The headaches and ocular pain had begun on April 23 after attending a theatre. She didn't care to eat and had one emesis that evening. On the following evening her vision had blurred until she was unable to read newsprint. She stated that she at first noted several blind areas which gradually fused together until the whole visual field was obscured. She had admitted "having a drink" on the night prior to onset of symptoms and wondered if this could have any relation to her blindness. She denied any contact with chemicals, dyes or varnishes and had taken no drugs.

Her past history was essentially irrelevant. She had diphtheria as a child of four with no sequelæ. Four months prior to her present illness she had given birth to a normal child. She had excellent obstetrical care including both prenatal and postnatal observation. There was no indication of toxemia. There was a slight "hydronephrosis of pregnancy" one week before delivery which responded to bed rest. Her postpartum blood pressure was 124/78. Her pulse, respiration and heart rhythm were recorded as normal. She was discharged from the hospital on the fifth postpartum day. One week before her present illness, she had a slight attack of pharyngitis which cleared up in a day or two. She had worn glasses for three years for a moderate hyperopic error. Her corrected vision had always been excellent.

On examination, vision with correction was reduced to counting fingers at 8 inches in the right eye and 20/200 plus 1 in the left eye and could not be improved. There was tenderness on pressure on the globes. The pupils were in mid-dilatation and reacted rather sluggishly to light. The extra-ocular movements were normal. The media were clear throughout. Both retinas showed a half dozen or so soft, fluffy, pale grayish patches of edema about ¼dd in size around each macular area. The nasal margins of the discs were partially obscured. The veins were a little over full. The visual fields were normal in outline and no central scotomata could be found, but there were several relative paracentral scotomata in either field. A diagnosis of toxic retinitis or neuroretinitis, of unknown origin, was made, and the patient was hospitalized on the following day where complete diagnostic study was made.

General physical examination, apart from the eyes, was negative except for marked sinus arrhythmia and a moderate exaggeration of the deep reflexes. The patient suffered excruciating headaches and orbital pain the first day in the hospital, complained of vertigo, and vomited once. Sodium salicylate and sodium bicarbonate were administered by mouth. Penicillin was given intramuscularly to combat any possible infectious agent. The headache and orbital pain were gone on the second hospital day but the globes were still tender. The pupils were widely dilated and failed to react to light or convergence. Vision was further reduced to bare hand movements in either eye. The patches of retinal edema coalesced until the whole macular and paramacular regions were diffusely edematous. The foveae were obscured. The discs became slightly hyperemic and the margins more blurred but were never appreciably elevated. On March 30 the patient complained of impaired hearing in the right ear. With it, she could hear a watch only at contact as compared to at 8 inches with the left ear. A neurological examination by Dr. L. R. Gowan on March 29 had been entirely negative except for the second and eighth cranial nerves. On April 2 the retinal edema began to recede and a faint greenish pigment tinge appeared in the paramacular regions. From this time on vision was rapidly recovered, and on April 9, the date of her discharge from the hospital, she could read one-eighth-inch type. The retinal edema was largely cleared, but several clumps of pigment were appearing in the paramacular areas, generally corresponding to the original patches of edema. The deafness increased.

X-ray examinations of the skull, paranasal sinuses and chest were negative. An electrocardiogram only confirmed the marked sinus arrhythmia noted clinically. Repeated urinalyses were negative. The white blood count reached 9,300 on one occasion. Red blood count was 4,390,000 and hemoglobin 13.5 gms. (95 per cent). Differential blood count was normal. Sedimentation rate was normal. Blood sugar was 93.0 mg., urea nitrogen 19 mg., and creatinine 1.5 mg. per 100 c.c. The Kline blood test was negative. Spinal fluid pressure, cell count, proteins and sugar were normal and the Wassermann negative. The blood serum failed to agglutinate B. melitensis or B. tularense, and agglutinated B. typhosis and B. parathyphosis only in 1:80 dilutions. Blood pressure was normal and temperature was normal throughout. On the basis of these essentially negative findings, it was considered that infection as the etiologic agent was highly unlikely.

After leaving the hospital she was examined at frequent intervals in the office. The pupils rapidly returned to normal. The retinal edema further cleared and vision continued to improve. On April 11 vision was 16/200 in the right eye and 20/200 plus 1 in the left eye. Visual fields were normal in outline and showed several small paracentral scotomata but no central scotomata. These scotomata corresponded generally with the areas of pigmentation. On April 22 corrected vision was 20/50 in each eye. However, there followed a slight relapse for two days, during which the eyes became tender and pained and vision fell to 20/200 and 20/65. This loss was rapidly regained during the next few days. On June 5 her vision was 20/30-1 in each eye. The fundi and visual fields had not significantly changed. There was a 60 decible hearing loss in the right ear. Pulse rate and rhythm were normal.

Until April 2, twelve days after the onset of symptoms, we were completely in the dark as to the etiology, when the patient volunteered the information that on the night previous to the onset of her symptoms she, with her husband, set out for a night of celebrating. They visited several hotel bars and night clubs and had eight or ten "or more" drinks of a mixture of bourbon whiskey and coco-cola. At the last stop, at a club of rather unsavory reputation, the patient complained that her drink tasted bitter and made her rather nauseated. She did not finish it for this reason. This revelation, together with the

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1947.

quite typical delayed onset of symptoms and course of the illness, led to the suspicion that her last beverage may have been contaminated with methyl alcohol.

Discussion

Methyl alcohol even in small quantities is known to produce severe grades of blindness. Ziegler[7] stated that one teaspoonful has been known to cause blindness. Methyl alcohol is a common adulterant of cheap liquor. It is incompletely oxidized in the body to formaldehyde and formic acid and the latter is very slowly eliminated. The formic acid is thought to produce an acidosis. Either formaldehyde or formic acid have been shown by Fink to act similarly to methyl alcohol itself and to produce, in animals, lesions in the ganglion retinal layer indistinguishable from those produced by methyl alcohol. The onset of symptoms in the writer's case—severe headache, orbital pain, nausea and vomiting twelve to fifteen hours after ingestion of a suspicious beverage—are quite characteristic. The sudden severe loss of vision, the dilated fixed pupils, and the rapid subsidence of these symptoms compared quite closely with most recorded cases of proven methyl alcohol poisoning in which recovery has occurred. Deafness has also been recorded many times.

Formerly, methyl alcohol was classed with other toxic agents, such as quinine, lead, ethyl alcohol, tobacco, carbon disulphide, iodoform, and arsenic compounds, which have a predeliction for the retrobulbar portion of the optic nerve and particularly the papillo-macular bundle and thereby give rise to central or caecocentral scotomata. In such cases, classified as retrobulbar neuritis, the opthalmoscopic picture is essentially negative or there may be seen only pallor or hyperemia of the optic disc. In many cases of methyl alcohol poisoning the toxin has acted in this manner. But there are other recorded cases which have not conformed to this picture. Moreover, histological studies in fatal cases have demonstrated that the chief and perhaps the primary lesion is in the ganglion cell layer. Birch-Hirshfield[1] concluded after histological studies that the primary lesion is in the ganglion layer and that damage to the nerve is secondary to death of the ganglion cells. Fink,[3] in experimental work on dogs and rabbits, has found extensive changes in the ganglion cells and relatively little damage to the nerve fibres. Schwartz,[2] who studied two cases histologically, found no damage to the optic nerves but found retinal changes which he considered responsible for the blindness. Menne[4] sectioned one eye from each of twenty-one fatal cases. I shall quote from this report: "Microscopically little change was observed in the optic nerves except for edema and hyperemia and some patchy proliferation of glial cells. The most prominent alterations were observed in the ganglion cells of the retinas: irregular staining, eccentric placement of nuclei, fraying of cytoplasmic outlines, vaculation and autolysis. In many instances only about one in fifty of the cells approached normal, while in some eyes they were entirely absent in wide areas. These changes in the ganglion cell layer were most marked nearest the disc."

From these reports of histological studies, all of which emphasize extensive destruction to the retina, one should expect to see some ophthalmoscopic evidence of this pathologic condition in cases of methyl alcohol poisoning. One wonders if this evidence isn't often overlooked, as the great majority of cases reported were not studied by opthalmologists. With the pupils widely dilated, the early retinal edema in the writer's case was overlooked by an intern until it was pointed out. Furthermore, as a large percentage of such patients die in the first few hours or days, pigment has not had time to migrate to the inner layers of the retina where it can be seen. In mild cases rapid recovery of a large percentage of vision might distract one from a careful study of the retina.

One may wonder why two or more people imbibing the same adulterated beverage would not be similarly poisoned. In answer to this, Casey Wood[6] stated that "Methyl alcohol is an example of idiosyncrasy. Some persons are largely immune as far as permanent damage to the organism is concerned. Of ten persons drinking 4 ounces of methyl alcohol within three hours, all will have marked abdominal symptoms and probably four will die. Six will recover, and two of these will be blind." It would seem that some individuals are capable of more completely oxidizing and eliminating methyl alcohol than others.

Merritt and Brown[5] reported a patient poisoned by methyl alcohol who had an attack resembling coronary occlusion on the way to the hospital. They found electrocardiographic changes and felt that the acidosis produced may have had a profound effect on the heart. The writer's case had a marked arrhythmia at the height of the toxemia which disappeared by the time the patient left the hospital.

Summary

In summary, a case of rather severe toxic amblyopia, accompanied with headache, orbital pain, vertigo, nausea and vomiting, has been reported. The paramacular regions of the retinas showed patchy edema becoming diffuse and later replaced with superficial patchy pigmentation. Approximately 90 per cent of vision was recovered. The etiology is unknown but the symptoms and course closely parallel the picture of mild methyl alcohol poisoning. References are cited to show that retinal pigmentation is not necessarily incompatable with lesions produced by this agent.

History of Medicine In Minnesota

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from January issue)

Frans Josef (later these names were anglicised to Francis Joseph) **Van Mackelenbergh** was born on April 7, 1834, in the historic city of 'S Hertogenbosch (Bois le Duc), in North Brabant, Holland, one of the five children of Frans Van Mackelenbergh and his wife. The Van Mackelenbergh family came of an ancient line in Holland; for many generations its members have been wholesale dealers in hardware, a firm whose traveling representatives have been known in every civilized country of the world except the United States. Of the Roman Catholic religion, the family has been characterized by devout faith and by generous giving to the church, both of its wealth and, in all generations, of its men and women to serve as priests and nuns. Since World War II started, nothing has been learned directly of the present representatives of the family in Holland and their interests; a Dutch refugee, a young woman who escaped to America via France and England, told members of the American branch (in 1943) that everything in the region in which the family resided had been confiscated by the enemy.

Frans Josef Van Mackelenbergh and his brothers received their early education in 'S Hertogenbosch, probably at the famous old grammar school at which Erasmus (1466-1536) once was a pupil. It was expected that in due time Frans would join his brothers, John, the eldest, Ambrose, and a third in the conduct of the wholesale hardware enterprise, and in preparation for this career and for the extensive traveling that would be part of it, he mastered five European languages, including English. When he was a young boy, he was busy during the summers in his father's business establishment; a few years later his vacations were spent in both educational and commercial pursuits when he acted as a salesman in the business, traveling through Europe and, on one occasion, to the Dutch East Indies. Already it had become evident, however, that business was irksome to Frans Josef and that he was interested rather in medical science, and accordingly his father sent him first to the University of Leyden to study in its world-known school of medicine and later to a medical school in France.

During his months in the Dutch East Indies and on the Malay Peninsula, in 1854, the student availed himself of the opportunity for scientific medical research and thereby obtained much interesting and useful knowledge. On the return voyage to Holland the ship was wrecked in a tropical storm and it was only after weeks of drifting in life boats (the entire voyage consumed three months) that the little group of survivors, of which Frans Van Mack-

elenbergh was a member, was rescued and taken to the island of St. Helena, off the southern coast of Portugal, until transportation home could be arranged. Correspondence of that period, preserved in the family records which recently have been translated into English, includes a letter from Frans' mother dated on January 7, 1855, which makes it clear that the boy had written home after a long absence and that news of him had given great joy to his family. In the following March his mother wrote with much concern regarding a dangerous illness from which Frans happily was recovering; this is the letter of a loving and devoutly religious mother. Another letter from her in the same month states that the visit which one of his brothers had intended to make Frans had been prevented by the most severe winter ever known in Holland. By April the traveler was able to return home.

Within the next decade there were changes in the family circle and in personal plans. The senior Frans Van Mackelenbergh died, as did one of his sons and a daughter. The eldest son John with his brother Ambrose succeeded to the headship of the family's mercantile company. Frans Josef Van Mackelenbergh, on his return from the East Indies, definitely had allied himself with the profession of medicine and had become a well-qualified physician whose chief professional interest then, as later, lay in the study of and treatment for chronic diseases. By the early sixties he had begun to look toward America as a new home and field for work and in 1866, immediately after his marriage to Magdalene Van Velthoven, like himself a member of a native Dutch family long in Holland, he sailed with his wife for America, en route to a Dutch settlement at Beaver Dam, Wisconsin. Arrived at Beaver Dam, Frans and Magdalena Van Mackelenbergh were disappointed to find that the Hollanders of that settlement were from a different province of The Netherlands than themselves and that variation in language made communication difficult. Having a friend, a Mr. Davis, in Waupun, Wisconsin, the young couple moved to Waupun for a few months, and in that village, in 1867, was born their first child, Francis Josef. Presently the little family moved to Chicago, where Dr. Van Mackelenbergh entered medical practice; in Chicago for a period of some length Mrs. Van Mackelenbergh, with the baby, lived at a convent where among the nuns she learned to speak English and to accustom herself to the strange manner of American life. It was during the years in Chicago that the second son, Ambrose, was born; this child died in infancy as the result of an accident when his nurse let the baby carriage plunge from the sidewalk over a high embankment. In 1871 a third child, Agnes Frances, was born.

Chicago was not a fortunate home for this family. There they first knew great sorrow. There, toward the end of their residence in the city, in 1870 or 1871, Dr. Van Mackelenbergh late one night as he was returning from a sick call was set upon by thugs who beat him severely and robbed him. And in the great Chicago fire of October 8 and 9, 1871, all their household goods and the doctor's offices and his entire professional equipment of books and instruments were destroyed. There remained to Dr. and Mrs. Van Mackelenbergh only the box of family goods and heirlooms which by happy decision they had left with their friend, Mr. Davis, in Waupun.

At this time of misfortune Dr. Van Mackelenbergh heard about an opening for a physician in the little hamlet of Greenleafton, York Township, fifteen miles southwest of Preston, in Fillmore County, Minnesota, and to this community, which had been founded in the fifties by a group of Pennsylvanians, representatives of the Dutch Reformed Church in America, Dr. and Mrs. Van Mackelen-

bergh came with their two children early in 1872. Again they encountered the embarrassment of difference in native language and, perhaps, lack of sympathy in religious belief, inasmuch as they were faithful Roman Catholics and Greenleafton was a settlement of Protestants. And again they sought a new location, which they found close at hand, in the village of Forestville. This little settlement was the center of a thriving and promising community of many substantial pioneers, the owners of good farms and comfortable homes. The village had an outstandingly fine general store and a flour mill, with the usual complement of mills of other types. In Forestville Dr. Van Mackelenbergh and his family were welcomed warmly and there they established their home and the doctor entered medical practice. In his old papers there appear the names, as friends and patients, of families that for generations have been well known in the county: Le Fever, Meighen, Foster, Storm, Reidell, Roeder, Kirvin and Winters, among others.

Dr. Van Mackelenbergh settled in Forestville about a year after Dr. Russell L. Moore had removed from the village to Spring Valley and probably at about the time that Dr. Henry L. Wilson moved to southwestern Minnesota. From the beginning he worked beyond his strength under the severe conditions of country practice of those years. At the time of his arrival there was in the community an epidemic of smallpox and subsequently there were sporadic outbreaks of diphtheria. He cared for the victims of these and other communicable diseases; dealt with chronic diseases, in which, it has been noted, he was particularly interested; with surgical emergencies; and with obstetrical cases. He sat up many nights in succession to watch by bedsides becauses nurses were few; cases are recalled even yet in which his skill and knowledge saved patients whom other physicians had given up to die. Because, other than the main stage route through Forestville, roads in the community were practically nonexistent, he traveled across fields and pastures and up and down the endless hills in horse-drawn sulky or buckboard or on horseback with his instruments and medicines in saddlebags. With all his gentleness to family and patients and his forgetfulness of self, he was a proud man; he loved to drive horses of pride and spirit equal to his own, and these horses, no more inured than himself to pioneer life, sometimes in their fright ran away and thereby endangered him twice over; on several occasions he was chased by wolves, twice he nearly froze to death.

In 1874 Dr. Van Mackelenbergh moved from Forestville to Spring Valley, perhaps because the former village had been left to one side by the Southern Minnesota Railroad and its fortunes unmistakably were declining, and because prospects were better in the latter settlement, which had become a railroad point. In Spring Valley, Spring Valley Township, on the western border of the county, knowledge of his skill in treatment for chronic diseases had preceded him and there he made many new friends. It was then that his professional card appeared in the local newspaper, *Western Progress:* "F. J. Van Mackelenbergh, Physician. Office at Cobb's Drugstore and at residence, two blocks south of the school house." In the next few years his announcements appeared intermittently, as did those of contemporary physicians, and it is worthy of note, for historical record, that in the printing his name underwent various changes and corruptions, as thus: F. G. Macklenbergh; F. J. Van Mecklenbergh; and F. G. McLenbergh. In this period also he was a patron of Andreas' "Illustrated Historical Atlas of the State of Minnesota," published in 1874, in which there appeared the entry: "T.

J. Van Mackelenbergh, physician and accoucheur." In the issue of 1880-1881 of a state gazeteer and business directory his name appeared correctly, but in the official register of physicians who were licensed in Minnesota during the period from 1883 to 1890, inclusive, in the section by counties, there is only the entry, "Exempt. Mecklenberg. Wykoff." It is recorded among documents in the possession of his family that after the passage of the medical practice act of 1883 Dr. Francis Joseph Van Mackelenbergh was licensed to practice medicine in the state under an exemption certificate.

Although Dr. Van Mackelenbergh prospered professionally in Spring Valley, it was there that the years of arduous practice began to take their toll of his health. And it was in 1880 and 1881 that little Agnes Frances began to give her father the help that was to continue the remainder of his life; driving his horses, sitting with him at the bedsides of patients, aiding him in the procedures of treatment and nursing. It is small wonder that after sixty-two years, memories still should be vivid of the pounding on the Van Mackelenbergh door at night when a relative of some sick person dashed up, usually on horseback, to summon the doctor; of the crawling out of bed and going into the dark barn to hitch up the horses, and of the driving out into the night. One trip after midnight was to the village of Fillmore, six or seven miles to the northeast, on the Root River, to attend an old soldier who was in great pain. Incidentally, payment for this visit never was made, and there were many comparable trips and many equally unprofitable visits to numerous patients in a widespread practice. Furthermore, the years in Spring Valley brought renewed and deep sorrow to the Van Mackelenbergh family. It was there, in 1879, that the eldest child, Francis Joseph (Frank), died at the age of twelve years, and that the fourth child, Roman Aldus, who was born in Forestville, on December 22, 1872, died at the age of ten years. Both children were buried in the Catholic cemetery at Carimona, in Carimona Township. Not long after the death of Roman Aldus the family moved, probably in the late summer of 1882, because of their grief, from Spring Valley to Wykoff, in Fillmore Township, about eight miles east of Spring Valley and about the same distance northwest of the former home in Forestville. In Wykoff sorrow pursued them, for in that village, on March 7, 1886, died Alphoso, the only remaining son, in his tenth year; burial was made in the Catholic cemetery at Carimona.

At Wykoff the hardships of county practice were not abated. There were continual exposure to weather; arduous trips on horseback or in vehicles over rough roads; lack of Sundays, holidays and recreation; lack of rest and sleep and proper food, because this physician, like many another early practitioner, took his meals when and where he could during his long rounds. The toll was heavy and Dr. Van Mackelenbergh's health progressively failed.

Francis Joseph Van Mackelenbergh died in Wykoff on March 18, 1892, in his fifty-eighth year. He was buried in the Catholic cemetery of the village. Some years subsequently his widow, Magdalena Van Velthoven Van Mackelenbergh, was married to Robert M. Foster, of Forestville. She died on April 26, 1921, aged seventy-seven years.

In 1943 the one surviving child of Dr. and Mrs. F. J. Van Mackelenbergh was their only daughter, Agnes Frances Rau, wife of George J. Rau, of Adams, Mower County. There were living also three granddaughters of the pioneer physician and his wife: Mrs. A. J. P. (Clara) Jelnik, of New Prague, Minnesota; Mrs. Alyce Vick, of Anoka, Minnesota; and Mrs. L. D. (Margaret)

McGuire, of Omaha, Nebraska. The great grandchildren were, in the Vick household: A. Thomas, Mary Jayne, Frances Ann and Marjean; and in the McGuire family: Richard, Terrance, Lawrence and Michael.

T. Veenschoten in the eighties is believed to have been physician and postmaster at the hamlet of Greenleafton, in section 1 of York Township, fifteen miles southwest of Preston. The little settlement was founded early by a group of pioneers representing the Dutch Reformed Church and it "was named in honor of Miss Mary Greenleaf, of Philadelphia, who generously gave three thousand five hundred dollars to build the Dutch Reformed Church edifice." Dr. Veenschoten's name has been observed by the writer only once.

Lyman Viall was born in New York State on December 18, 1818, and was one of a family of seven children, his brothers being Milton, Frank, Mulford and Andrus and his sisters Hulda and Aurella. He received his early education in the schools of his native place and when a young man came with other members of the family into the Mississippi Valley during the exodus from east to west that took place in the middle decades of the nineteenth century. Two of the brothers, Frank and Andrus, settled eventually in Wisconsin and another two, Milton and Lyman, in Minnesota.

It is probable that Lyman Viall received his medical training primarily under a preceptor, as was the custom at that period. Subsequently he studied at a medical school of the regular system in Chicago, perhaps, it has been suggested, at Rush Medical College. His name has not been observed in medical directories or in medical registers.

Dr. Viall first practiced medicine in the vicinity of Downer's Grove, Chicago, for an unknown number of years. By an early marriage, either in the East or in Chicago, he had two children: Mary (afterward Mrs. Ober) and J. Burke Viall. After the death of his first wife he was married, on October 5, 1858, at Brush Hill, Illinois, sixteen miles from Chicago, to Helen C. Gage, who was a native of Wood County, Ohio, born on November 29, 1831. Of the second marriage there were four children: James Gage, Bard Ellsworth, Ralsy Edward and Harry Lyman. In adult years James Gage became a brick layer, Bard Ellsworth a banker, Ralsy Edward an employe in the steel mills and Harry Lyman an electrician.

Dr. Viall has been mentioned as being in Winona, Minnesota, in the late fifties, and it was not long after that time, in 1860 or 1861, that he settled on a farm three miles north of Spring Valley, Fillmore County, in the community in which his brother, Milton Viall, also established a home. For nearly ten years Dr. Viall farmed, applied his skill as an excellent carpenter and, from his home as an office, carried on a general medical practice, locally and at considerable distances as required. He must have had unusual success in treatment for smallpox, because he has been recalled in the region as a "smallpox specialist"; and in a subsequent period, in Preston, much of his professional activity had to do with the disease. One of his sons has the vivid memory from childhood years of seeing his father many times ride away on horseback and of knowing that his destination was a home where someone had smallpox. Dr. Viall himself, when yet in Illinois, was a victim of the disease. The local authorities placed him in the pest house and there he underwent a serious illness and a stormy convalescence, stormy in more senses than one, for the roof of the pest house was not weatherproof and during heavy rainstorms the

water poured through upon the patient. It may well have been that his interest in smallpox and the proper care of sufferers from the disease dated from that time.

Early in 1869 Dr. Viall settled in Preston and in March, on the outbreak of smallpox in the village, he promptly was constituted health officer, the house in which the patients lay was declared a hospital by the local board of health, and Dr. Viall was "required to procure suitable nurses for the sick in said hospital and to do such other things as may be necessary under the premises." His interest and success in the treatment for smallpox continued throughout his practice, as evidenced by many notes in the local newspapers. In June, 1882, the *National Republican* commented that Dr. Viall had another smallpox case on his hands. The patient was one of a Norwegian family of eight or nine children, none of whom could be induced to be vaccinated. The editor added that "they think the doctor is working up a system out of which to make money. . . . Proper precaution is indicated."

Among Dr. Viall's numerous medical contemporaries in the village were Lafayette Redmon, John A. Ross, Henry Jones, O. A. Case, George A. Love and, in the early eighties, J. H. Phillips. Dr. Viall was a member of the Universalist Church, a good and respected citizen, reliable in his professional work and in the conduct of his business interests. He was the owner of his home and of other real estate. Two of his outstanding characteristics were that he read widely, especially history, and that he always was well groomed and so smartly clothed as to be called dressy.

After fifteen years in Preston Dr. Viall died on September 23, 1885, of "paralysis of the brain," his son has stated. After his death Mrs. Viall, an intelligent and able woman who had always been interested in medical matters, took up midwifery and practical nursing and for several years served the community successfully as a skillful practitioner. Helen Gage Viall lived thirty-eight years after her husband's death and died in Preston on November 16, 1923.

In 1943, of Dr. Viall's immediate family there were living his sons, James Gage Viall, of Phoenix, Oregon, and Ralsy Edward Viall, of Granite City, Illinios, and their twelve grandchildren, several great-grandchildren and nieces and nephews.

P. Von Lackum, "physio-medical physician and surgeon," settled in Preston in December, 1869, and announced that he used no noxious substances whatever in his practice and claimed for his system of medicine more efficacy against disease than that of any other.

Early in 1871 there appeared at considerable length in the local *Republican* editorial versions of one of Dr. Von Lackum's cases that made most interesting reading. It seemed, on first account, that the practitioner was called to see a Norwegian girl, living at home in a neighboring community, who suffered greatly, her distress manifested by writhings and contortions; that the doctor decided that she had drunk water from a pond containing "wiggle-tails"; that the creatures subsequently had changed to frogs in great numbers within her stomach; that the doctor wished to open the stomach; that the parents of the girl refused the operation. After much speculation the reporter challenged science "to vindicate" if frogs actually were in the stomach, "by showing how they came to subsist there through the gradations from the diminutive wiggle-tail to a full grown croaker with propagating powers other than those

it would enjoy in the bogs and ponds in which it has, from time immemorial, given its delicate note to the night breeze." All was made clearer a few weeks later by the following communication from the patient's brother, published at the doctor's request: "I hereby certify that Dr. Von Lackum never said there was frogs in my sister's stomach. The doctor said that it might be a frog or a lizzard. The doctor never called other physicians for a consultation in this case and never said anything about operating on her. Dr. Von Lackum was called for consultation after the other physicians could not make out what her ailing was."

The editor added, regarding Dr. Von Lackum: "He also unhesitatingly affirms it as his belief that snakes, toads and lizards may subsist in the human stomach to the great discomfort of those who may become burdened with them, in view of which we reiterate the opinion that Dr. Von Lackum is in error and science must vindicate."

Evidence did not appear that this practitioner afforded further challenge to science. His professional cards were not noted by the writer in issues of local newspapers subsequent to March, 1872.

This absurdity is given because of its obvious significance. In Minnesota, as elsewhere, there were practitioners of sorts who prospered until adequate acts to regulate medical practice came into effect.

In 1874 there was residing in the city of Winona, Winona County, Dr. Peter Von Lackum (since said to have been a botanic physician and surgeon), who practiced there about four years. This man came from Germany and first settled in Minnesota in 1864, according to Andreas' *Historical Atlas* of 1874. It is probable, but unproved, that this man and the physio-medical physician and surgeon of Preston were the same.

Charles Carroll Walker was born in 1870 at Kilbourn City, Wisconsin, the son of Luzern Walker and Christiana McCumber Walker, both of whom were natives of New York. There were four other children, all boys, William E., L. T., F. H., and Raymond M. Walker.

Charles Walker obtained his early education in the schools of Kilbourn City. Immediately after his graduation from the local high school, in 1888, he had a year of academic and premedical work at Lawrence University, at Appleton, Wisconsin, and subsequently matriculated at the Northwestern University Medical School, from which he was graduated in 1896.

Licensed in Minnesota by examination, in 1896, Dr. Walker practiced two years in Winona before settling, in 1898, in Chatfield, Fillmore County. In 1900 he moved to Lamberton, Redwood County, where for the greater part of the last forty-three years he has been engaged in general medical practice. In the summer of 1906, then in Currie, Slayton County, he took a postgraduate course in Chicago before returning permanently to Lamberton. He is a member of the Methodist Church, has served on the city board of health, and in 1918, in World War I, was a captain in the Medical Corps of the United States Army.

On June 4, 1903, Charles Carroll Walker was married to Julia Cole, of Chatfield. In 1943, of Dr. and Mrs. Walker's three children, Charlotte was deceased, Kathryn was Mrs. W. J. Smith, of Denver, Colorado, and Harold E. Walker, of Duncan, Oklahoma, was in the United States Army.

(To be continued in March issue)

President's Letter

IT'S YOUR ASSOCIATION

The Minnesota State Medical Association, like any democratic body, can best fulfill its function and objectives if its individual members are all fully aware of the makeup and mode of operation of their representative group. The State Association is a federation of thirty-three county medical societies throughout the state, having a membership of more than 3,000 physicians. It is a constituent state unit of the American Medical Association.

The most important figure in the Association is not the president, but the individual practicing physician. He is the fundamental unit of the entire structure of organized medicine at all levels—national, state and local—for that is the way in which free men organize themselves democratically. Authority does not come from the top down; authority springs from the individual member, who through his county medical society makes his ideas and desires known.

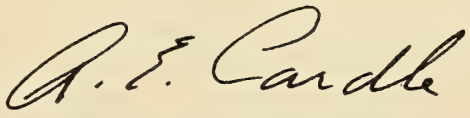
The most potent force in the State Association is the local county medical society. Each local society elects delegates who in turn compose the House of Delegates. Supreme authority is vested in the House which meets annually at the time of the annual scientific meeting (unless called into special session). This body is presided over by an elected speaker. In addition, the House of Delegates elects a council, which in the interim has full power and authority. The Council consists of nine members—one member from each of the nine councilor districts plus six other *ex officio* members who may sit with the Council but who do not have the right to vote. These are the president, the immediate past president, the president-elect, the secretary, the treasurer and the speaker of the House of Delegates.

Association affairs are managed by a full-time executive secretary and his staff of assistants, with headquarters at 496 Lowry Medical Arts Building, Saint Paul. Your Association is to be complimented on having at the present time one of the finest executive secretaries in the country, and much of the success of the organization can be attributed to his diligent and untiring efforts. Every member should make a point of becoming acquainted with the executive secretary. His duties consist of carrying out the directions of the House of Delegates, the Council and the thirty-nine appointed scientific and economic committees.

The state office is working full time for the interest of the medical profession and furthering the activities of the Association and is anxious to give assistance in any way possible to any member who desires it. For example, the office maintains a speakers' library, material from which can be sent to physicians on request when they have been called upon to address a lay group and desire accurate up-to-date information to use in preparing a talk. The headquarters office keeps an alphabetical file of Minnesota physicians with whatever biographical data is available on each one. There is also a placement service for physicians seeking locations or looking for assistants or associates. Suggestions from members on how the program of the Minnesota State Medical Association can be improved or expanded are welcomed. Effort is

made to acknowledge all such communications promptly, and matters requiring consideration by the Council or a committee will immediately be referred to the proper group.

In addition, the Association maintains the services of a trained and skillful attorney, who is responsible to the Council and is actively engaged in handling the legal matters pertaining to the activities of the Association.



With his license to practice, with the approval of his fellows and with all of the qualifications for membership defined in the Constitution and By-Laws adequately met, a physician becomes a member of the medical society of the county or district in which he resides. This automatically makes him a member of the State Association. From that point it is his responsibility to keep his membership, to see that he gains the maximum amount of benefit from this membership and to make a genuine effort to contribute to the work of the organization. It should be the duty of each member to take a vital interest in the affairs of the State Association, for by so doing he has his best opportunity to keep abreast of medical developments and to improve his service to his patients and humanity. As a member of a scientific committee he can help educate the public in health matters in many different fields. By service on an economic committee he can help stimulate such activities as the extension of medical service in rural areas or see that sound health legislation is passed which will safeguard the health and welfare of the people of the state. A physician can also make valuable contribution by serving as a delegate from his society, as a Council member or as an Association officer.

The activities of the Association are many and varied. The annual scientific meeting attempts to provide its members with one of the best-rounded medical programs possible. Through Minnesota Medicine, the official journal, members have the opportunity of reading one of the finest state journals published. Not only does it provide scientific information, but also pertinent news on a national and local scale, to keep members posted on all current matters. A monthly news letter further augments this information. Every member should give his most careful attention to these if he wishes to contribute to the organization and derive the benefits it has to offer.

The Association also provides speakers and exhibits for lay gatherings; distributes sound, scientific health information to the press and radio; distributes literature and co-operates with and supplies professional advice and guidance to responsible official and voluntary agencies and organizations whose activities also lie in the health field.

It also provides members with an opportunity to join in organized action on matters pertinent to public health and medical practice, serving as a clearing house for information for members of the medical profession and, to some extent, the lay public as well.

The local societies and the State Association will be only as active, alert and effective as are the individual members. No member is too young or too old to serve, or to give his ideas on how the program of the Minnesota State Medical Association can be improved or expanded. Your interest and suggestions are essential to the success of the group. It's *your* Association.

President, Minnesota State Medical Association

TRENDS IN MEDICAL PRACTICE

IT is sometimes possible to see certain trends in the practice of medicine. When such a trend is not a healthy one, attention should be called to it so that it can be corrected.

The average physician enters the practice of medicine because of interest in the science and art of medicine and because he has a certain altruistic desire to be of service to people. This is as it should be and should be the universal urge in selecting medicine as a vocation. One who selects medicine as a road to wealth is most likely doomed to disappointment. Only the very few acquire wealth in the practice of medicine. Those who do are likely to pay for their financial success in overwork and short lives.

On the other hand, the practice of medicine offers a good living to the industrious and serious minded physician. This is particularly true in the case of general practice, whether the young physician settles in the city or the country. With the present-day surge among recent medical-school graduates towards specialization, it can be safely predicted that a certain proportion of specialists who are for the most part located in the larger centers of population will be forced for economic reasons to shift to general practice in locations where they are needed.

While we do not decry the obvious need for specialization in medical practice and the desirability of certification of specialists by National Boards, specialization is being overdone. Greater financial compensation of certified specialists, obvious in government payrolls, has doubtless been the main factor in the overproducing of specialists. Government financing of GI's in enabling them to specialize, while possibly a temporary factor, accounts for the situation in some hospitals where there are two residents training for the specialties for every intern. The obvious remedy is the limitation of available residencies. We feel sorry for the young doctor who invests three to five years of training in a specialty when a year or two in preparing for general practice would have been the wiser choice. A few years of general practice enables the young doctor to know better what specialty to choose and, in our opinion, a general practitioner should be given preference in the filling of residencies. One who has been in general practice knows that there is more to a patient than that organ or organs with which he as a specialist deals.

One of the regrettable results of specialization is the frequent difficulty a sick and perhaps acutely ill person often has in obtaining prompt medical care even in a large city that boasts hundreds of doctors. The doctor called is a specialist, and from the description of the symptoms, the case is not in his line or he doesn't make house calls or night calls. Instead of having any feeling of responsibility as a member of the healing profession in seeing to it that the patient contacts a general practitioner who will respond to the call, he hangs up the receiver. What a simple matter for the specialist to have the names of several general practitioners to whom he can refer calls. Or are general practitioners already so scarce that he knows of none?

We talk about the need of improving our public relations and the need of contributing to the support of publicity agents who will extoll the accomplishments and virtues of the profession, when the very best public relations are established by the individual physician in his relations with the public. As someone has said, adherence to the Golden Rule by every member of the profession would obviate the need for any other public relations agency. Are we losing some of the idealism which has always been a part of medicine and has distinguished medicine as a profession in contradistinction to a business?

The laborer is worthy of his hire, but financial return should be secondary to service.

AMERICAN RED CROSS

IN March, the Red Cross will again collect funds to support its various relief activities. Americans gave generously to the Red Cross during the war and will doubtless continue to support

it in contributions of time and money during peacetimes.

During 1947 the Red Cross assisted the sufferers from the Texas City disaster with more than $1,000,000 and the September hurricane victims with an additional $1,000,000. During the first ten months of the year, a sum of over $9,500,000 was appropriated for the disaster sufferers. More than 2,000,000 cases involving veterans and their dependents were handled during the past year, involving nearly $12,000,000 in expenditures. In addition Red Cross personnel are making life brighter for inmates of veterans hospitals. Educational classes in first aid and the blood banks which are getting under way are other worthwhile activities of this famous organization. *Give!*

MEDICAL COSTS AND OTHERS

FRANK G. DICKINSON, Ph.D., Director of the Bureau of Medical Economic Research of the American Medical Association, has made an interesting analysis of medical costs in recent years in relation to certain other living costs. He divides medical costs into those for physicians' services, hospital and other medical costs. The costs of physicians' services include only those in private practice, and the hospital item includes only payments to proprietary hospitals and the operating expenses of nonprofit hospitals.

He shows that by 1945, the expenditures for physicians' services had increased over the average expenditures for the years 1935 to 1939 some 163 per cent; hospitals, 180 per cent; and total cost of medical care, 188 per cent. By comparison, expenditures for alcoholic beverages had increased over the same period, 248 per cent; recreation, 253 per cent; tobacco, 176 per cent; personal items, 229 per cent; and jewelry, 380 per cent. He shows that in comparison with expenditures for the items mentioned the amount spent for physicians' services has increased the least. Or to put it in dollars, the amount paid in billions for physicians' services increased from 0.8 for the basic period of 1935 to 1939, 1.3 in 1945; for hospitals, from 0.4 to 0.8; medical care from 2.6 to 5 billions. During the depression years, the cost of physicians' services, hospital care and total medical care took the highest percentages of the personal income that it has since 1929. This is to be expected, as the services of physicians and hospitals are in the nature of a necessity.

This finding of less fluctuation in the income of physicians as a whole, in comparison to other items, is in keeping with experience. Many physicians have not increased their fees at all, others only moderately, although the overhead cost in their practice has increased some, and, of course, their cost of living has about doubled, as it has for everyone else. Medical fees paid by insurance companies and for industrial work have remained stationary for the most part, and these rates set a standard to some extent for private practice.

The following figures are of interest. The total consumer expenditures of 143.7 billions in 1946 were approximately double the figure of 72.1 billions in 1940. This includes 8.8 billions spent in 1946 for alcoholic beverages as compared with 3.6 billions in 1940; 7.9 billions for recreation in 1946 compared with 3.7 billions in 1940; 5.6 billions for total medical care in 1946 compared with 3.1 billions in 1940; 1.4 billions for jewelry in 1946 compared with 0.5 billions in 1940; all this compared with 1.5 billions spent for religious *and* welfare activities in 1946 compared with 1 billion spent in 1940.

These figures do not mean that we as a nation are drinking twice as much alcoholic beverages as six years ago. Much of this item is due to high cost of production and higher taxes. They do not suggest, however, that we are drinking any less. We apparently must have our liquor whatever the cost. To spend nearly six times as much for liquor, five times as much for recreation and nearly as much for jewelry as we spend for religious and welfare activities combined does not speak well for our ideas of relative importance.

As Dickinson says: "Medical care is expensive; it is becoming more expensive; yet as a percentage of national income in a period of frenzied prosperity, it is a shrinking item. Medical care is expensive, but patients are getting more for their money in terms of longer life."

THE MINNESOTA CANCER CONTROL PROGRAM

AS Minnesota physicians are aware, never before in history have such extensive and well-planned efforts been directed at seeking the cause and cure of any disease as are now being leveled at cancer. In Minnesota, the cancer program has recently been expanded by setting up, in the State Department of Health, a Division of Cancer Con-

trol, established when federal cancer funds were made available to state health departments in 1945.

Despite the fact that large sums of money are being spent on cancer research and many highly skilled persons are diligently seeking for clues to a solution of the problem of cancer, we still have to rely on time-tested, though none too satisfactory, procedures for treating cancer. Prevention is still a hope for the future. Early detection and early, adequate treatment are the only measures that offer real hope at present of reducing our high cancer mortality.

Definite progress has been made toward early detection through educating the lay public to be on the alert for early signs of cancer and to report such signs promptly to their physicians. But that is only the first step. The second step, equally important, consists of providing prompt and effective treatment. That step must, of course, be taken by physicians themselves. They must be ready and able to apply all measures necessary to determine if cancer is present. This they can do only if proper facilities for examination are available, including special training for the physician if necessary. If prompt diagnosis is made, then early treatment will follow as a matter of course.

In co-operation with the Cancer Committee of the Minnesota State Medical Association and the Minnesota Division of the American Cancer Society, the Minnesota Department of Health is now setting up a program that will aim to meet the requests of physicians for greater knowledge concerning cancer. This program will undertake to provide:

1. Educational opportunities for graduate students in cancer
2. Refresher courses on cancer for practicing physicians
3. Speakers on cancer control for meetings of medical societies and hospital staff meetings
4. A correspondence consultation service for physicians

The Cancer Control Division of the Health Department is also undertaking, through hospital reporting of cancer cases, a statewide statistical study of the incidence and distribution of cancer. The information gained from this study will be made available to physicians as rapidly as significant data are accumulated.

DEAN S. FLEMING, M.D., M.P.H.

Dr. Fleming is Chief of the Section of Preventable Diseases, Minnesota State Department of Health.

MEDICAL MOTION PICTURES

IT is not generally known that the Committee on Medical Motion Pictures of the American Medical Association has some 4,000 motion pictures available gratis, except for transportation charges, for use at medical meetings—hospital staff, county or state. About 50 per cent of them are sound pictures, most of them on the postgraduate level. The service was organized in 1945, reviews of new acquisitions appear in the A.M.A. Journal, and a catalogue is available for use in selection of the subject desired. At present, most films presented at medical meetings are those furnished by pharmaceutical houses. Society secretaries interested in securing the AMA pictures should write Mr. Ralph Creer, Secretary of the Committee on Medical Motion Pictures at A.M.A. headquarters, 535 North Dearborn Street, Chicago 10, Illinois.

RESEARCH PROJECT ON CARDIOVASCULAR DEGENERATION

The Laboratory of Physiological Hygiene of the University of Minnesota's School of Public Health is undertaking a long-term study of physiological factors involved in human cardiovascular degeneration (arteriosclerosis and hypertension). Special attention is being given to the effects of dietary and activity habits, and efforts are being made to include some evaluation of personality characteristics. This project is sponsored by the U. S. Public Health Service, acting on the recommendation of their cardiovascular advisory committee (Dr. W. Cowles Andrus, chairman). The program has been endorsed by the Heart Committee and the Council of the State Medical Association and the Ramsey and Hennepin County Medical Societies.

A major part of the program consists of systematic periodic examinations and tests of men who are "normal" at the time of their first examination. In a total of 500 men who are participating approximately 200 are University students (eighteen to twenty-six years of age) and the remainder are businessmen recruited from the Twin City area whose ages are forty-five to fifty-four, inclusive.

The examination, which takes about four hours, includes the following items: (1) special history and physical examination, designed to reveal cardiovascular abnormalities; (2) electrocardiogram (4 leads); (3) X-ray and fluoroscopy of the chest; (4) hemoglobin estimation; (5) serum cholesterol determination; (6) urinalysis; (7) estimation of peripheral circulatory impairment by reactive hyperemia; (8) pulse wave velocity (an index of the elasticity of the general arterial tree); (9) studies on the response of blood pressure to light exercise, to cold (cold pressor test) and to 6 per cent carbondioxide inhalation; (10) estimation of the fat content of the body by the densitometric method; (11) an-

thropometric measurements of skeletal size and of skin fold thickness in standard locations; (12) personaltiy evaluation (Minnesota Multiphasic test); (13) activity and dietary history.

It is planned to administer this battery of tests once a year to the volunteers for five consecutive years. After this time, status of these men will be checked by the usual follow-up methods for an additional five years. At this time an effort will be made to have all the available men undergo a physical examination to obtain their status in terms of current medical practice. It is expected that it will be possible to correlate the several biochemical, physiological and psychological measurements and the relevant items in the activity and dietary history with the subsequent development of arteriosclerotic and hypertensive cardiovascular disease in these men. It is hoped that from this work it will prove possible to identify the persons who are more than usually likely to have trouble in this respect, to discover factors in the mode of life which are predisposing and to provide indications for a preventive hygiene.

In addition to the long range studies described above a large number of experimental studies on other subjects and patients will be made to develop methods, test hypotheses and to provide validating criteria. Current activities in this part of the program include systematic researches on reactive hyperemia, on cholesterol metabolism, on the estimation of body volume, on renal blood flow in rest and work, on personality and emotion in relation to circulatory function with special emphasis on vasomotor instability and on exercise in hypertensive patients.

This program is being operated by the Senior Staff of the Laboratory of Physiological Hygiene: Drs. Ernst Simonson, Olaf Mickelsen, Austin Henschel, Henry Longstreet Taylor, Josef Brozek and Carleton Chapman and the Director, Dr. Ancel Keys. Part time associates in this program include representatives from the Departments of Medicine and Neuropsychiatry. The organization of the operating personnel in this project is based on the concept of interdisciplinary research. The team which is operating this program brings to bear on this major problem the skills and knowledge derived from the following disciplines: biochemistry, physiology, psychology, medicine and psychiatry. It is felt that only through the co-ordinated efforts of a number of specialists can a well-rounded solution of such a complex problem be achieved.

Every effort is being made by the investigators to work with the members of the local medical profession. There is no intent on the part of the Staff of providing medical care or advice to any of the men participating. In each case, the physician is notified that his patient has volunteered for this experimental program. It is emphasized to the participants that this data is being collected for scientific purposes only. If any abnormalities are found, the information is transmitted to the personal physician of the participant and the participant is told to consult his physician for advice and treatment. All findings and data are available to the personal physicians of the subjects.

HENRY L. TAYLOR, M.D.

MINNEAPOLIS HEALTH STATISTICS

A new all time high for births occurring in Minneapolis was set in 1947 with a total of 17,549, Dr. F. J. Hill, Commissioner of Health, reported today. The next highest record was in 1946 with 15,682 births. The total for 1947 includes 4,928 babies born to non-resident mothers compared with 4,169 in 1946. Though the monthly reports of births started a downward trend last August, the total for the year remained the highest on record. Boys continue to arrive more often than girls. In 1947 there were 855 more boys than girls born.

Even with over 17,000 babies being born during 1947, the city experienced outstanding low rates for infant mortality and deaths of mothers in childbirth with 25.7 per 1,000 live births and 0.5 respectively compared to 26.6 and 0.7 in 1946. "These are signs of good community health" stated Dr. Hill. Prematurity is the leading cause of death of infants under the age of one year, and particularly in the first month of life.

Deaths from all causes among residents increased slightly, being 4,657 in 1947 as compared to 4,473 in 1946. The over-all death rate was 9.1 per 1,000 population compared to 8.8 in 1946.

The preliminary figures show no change in ranking of the ten leading causes of death as compared to 1946 with the exception of tuberculosis and nephritis which exchanged positions, namely 9th place for tuberculosis and 10th for nephritis. Heart disease, cancer, apoplexy, diabetes, and nephritis continue to account largely for increase in the total number of deaths from all causes during the year. With the percentage of our population over 45 years of age increasing annually, we anticipate a higher death rate from degenerative diseases.

The incidence of certain communicable diseases increased in 1947, but there were no major epidemics as in 1946 with poliomyelitis. Whooping cough with 534 cases resulted in one death compared to 52 cases and no deaths in 1946; measles with 2,107 cases with one resident death compared to 410 cases and no deaths in 1946.

Considerable progress was made in diphtheria control during the past year with a reduction in deaths from 7 to 1 in 1946 and 1947, respectively. The drop from 110 cases of diphtheria to 58 was also noteworthy but still unenviable since the disease has been even more successefully controlled in other communities. Investigation of cases reveal that preventive "shots" had not been arranged for by parents.

As predicted during the polio epidemic in 1946 that there would be few cases in 1947, we had only 21 resident cases and 3 deaths in 1947 as compared to 763 resident cases and 47 deaths in 1946.

The increase in the number of reported cases of tuberculosis is largely attributed to an outgrowth of the Community-wide Chest X-ray Survey. The 1,022 reported cases of tuberculosis in 1947 as compared to 615 in 1946 reflects this intensified case-finding program. The increase in the tuberculosis death rate from 18.3 per 100,000 population to 20.5 in 1947 cannot be explained without a study of many factors. Because of the intensified case-finding program and the number of sus-

of the
Minnesota State Medical Association
George Earl, M.D., Chairman

MEDICINE'S RECORD IS ANSWER TO TRUMAN PLEA

When, as was expected, President Truman's State-of-the-Union address to Congress on January 7 contained another plea that something be done to fill the "gap in our social security structure" created by the "lack of provision for the nation's health," the medical profession already had an answer—one recorded not in words but in positive action.

This answer was reviewed by the House of Delegates at the Cleveland interim session in January. It consists of a detailed progress report, prepared by the Board of Trustees of the American Medical Association, on what has been done toward achieving the objectives of the Association's ten-point national health program. The simple and unmistakable conclusion from the report is this—*a lot has been done!*

Briefly, the major accomplishments of the medical profession have been along the lines of extension of prepayment programs, both medical and hospital; continual advancement of scientific research; intensive public health education; support for needed and well-founded health legislation; and co-operation with responsible groups in an all-out effort to extend high quality medical and health care to all people.

Again Demands National Program

Recognizing that American medical standards are high, President Truman repeated the oft-heard contention that "most of our people cannot afford to pay for the care they need."

"I have often and strongly urged that this condition demands a national health program," said Mr. Truman. "The heart of the program must be a national system of payment for medical care based on well-tried insurance principles. This great nation cannot afford to allow its citizens to suffer needlessly from the lack of proper medical care." Conspicuously absent from the presidential message was the word "compulsory." However, there is not the slightest evidence that Mr. Truman has changed his mind on compulsory sickness insurance, federally administered, as his solution to national health problems. At any rate, compulsion is not consistent with the American ideals of freedom which Mr. Truman says he wishes to see maintained. The medical needs of the American people are far more effectively met on a local community and state basis rather than by a system centrally controlled. The ideals of freedom are better protected on that basis also.

One in Three Now Protected

Mr. Truman neglected to mention that many millions of Americans are already protected against the costs of hospitalization and sickness by the Blue Cross Plans, the physician-sponsored voluntary plans for paying the costs of medical care and the contracts sold by long-established private insurance companies. Already the American people are well on the way toward meeting the President's standard of "a national system of payment for medical care based on well-tried insurance principles."

As of December, 1947, the latest date for which there are figures, about *one American in every three* had some form of insurance against sickness costs. A study conducted by the National Industrial Conference Board has revealed that at the end of 1947 total enrollments in voluntary plans — commercial and physician-sponsored, group and individual—topped the 61 million mark. Some duplication exists, the study showed, as for example the medical plans often require subscribers to purchase Blue Cross contracts along with medical coverage; but the above figure was reached with a liberal allowance for such overlapping. It was the conclusion of the Conference Board that so much attention has been diverted to socialized medicine that the phenomenal expansion of voluntary health protection has been overlooked. President Truman might well take note

that his request for "some kind of national health program" is already being filled—the voluntary way.

Welfare Department Idea Reappears

The idea of having a new department in the federal government to look after the welfare of the population cropped up again in the President's address. Physicians will recall that last February the Taft-Fulbright bill (S.141) to create a Department of Health, Education and Security was introduced in the Senate. This bill outlined the very thing President Truman had reference to when he said: "The government's program for health, education and security are of such great importance to our Democracy that we should now establish an executive department for their administration."

The plan to set up such a department did not fare too well in the last Congress, however; and what the President's chances are of seeing his present request filled during the coming year is not known.

S.141, advocating the three-cornered departmentment, was referred to the Senate Committee on Expenditures in the Executive Departments, where it languished for over a month. Opposition was expressed by the American Medical and Dental Associations and other organizations; hearings were concluded with the bill failing to be reported out of Committee.

Object to Third Party

The medical profession's objection to a Health, Education and Security Department stems from its creation of a third party between the medical profession and the President. The plan would create a Secretary of Health, Education and Security, under whom there would be three undersecretaries, one for each of the three major divisions. The handicaps under which an Under-Secretary of Health would have to operate are obvious. For example, he could get no action directly from the Chief Executive; he would have to discuss health and medical programs, legislation and policy with the President through an intermediary—someone, perhaps, from the welfare or social insurance fields.

For many years the medical profession has favored assembling and co-ordinating all health functions of our national government in a single agency with an administrative head in the Presidential cabinet. The profession does *not* favor combining health, education and security in one department if it means subordinating health matters and forcing medicine to play a subsidiary role. If health is, as many statesmen have declared, a primary consideration of government, then it should warrant a separate department with the distinction of cabinet rank for its chief.

AMA Working to Obtain Objectives

The genuine effort of the American Medical Association to "get its ten-point program off the printed page and into actual practice," as it was outlined to the House of Delegates at Cleveland, stands as the best possible refutation of the claims made by Mr. Truman and others which create the impression that America is in dire straits, medically speaking.

The ten-point program of the AMA is a restatement of a fourteen-point program officially adopted in June, 1945. It has been offered as organized medicine's solution to the national health problem; in it the basic health needs of this nation are clearly outlined and the methods whereby these needs may be met are advanced.

Diametrically opposed to regimentation or any form of totalitarianism, the medical profession suggests the following as fundamental to good health: (1) minimum standards of nutrition, housing, clothing and recreation; (2) provision of preventive medical services through professionally competent health departments; (3) availability of procedures established by modern medicine for advice to the prospective mother and adequate care in childbirth; (4) proper attention including scientific nutrition, immunization and other services included in infant welfare for all children; (5) provision of health and diagnostic centers and hospitals necessary to community needs; (6) establishment of voluntary non-profit, prepayment plans for meeting costs of hospitalization and medical care; (7) high-type medical care for all veterans, preferably by a physician of their own choice, with payment by the government in cases where disabilities are service-connected; (8) research for advancement of medical science with endorsement of a National Science Foundation; (9) encouragement of participation in national health program of volunteer philanthropic health agencies; and (10) promotion of public health by widespread education and dissemination of information regarding prevention of disease and its proper treatment.

Pioneers in Health Education

In implementing the ten-point program, the American Medical Association has literally spared no efforts. For example, a look at the health education program which it carries on will bear this out. A pioneer in the field of public health education, the AMA is continually expanding and augmenting its program and utilizing all communication media—radio, newspapers, magazines, the speakers' platform, pamphlets, books, motion pictures, personal correspondence—and lately, television.

In addition the Association sponsors conferences, lends its personnel and members to other agencies and organizations as consultants or advisors or committee members, provides scientific exhibits for organizations requesting them. At present the AMA is actively co-operating with over thirty national agencies and organizations and its members serve on some twelve national committees. The AMA publishes articles on health and fitness in ten periodicals, including its own publication, *Hygeia;* answers an average of 2,500 letters a year on health problems; and issues health releases to about 2,000 periodicals and newspapers. Literally millions of books and pamphlets on health have been published by the AMA. Extension of education in health to schools in every grade and recognition of health education as a subject to be assigned for credit has also been urged.

A special campaign waged by the AMA has been its constant emphasis on the importance of the periodic health examination. It publishes a standard manual in this field and furnishes examination blanks; it employs every editorial channel available to promote recognition of the value of the periodic physical to preventive medicine.

Conducts Surveys, Promotes Research

Two other activities which medicine has undertaken and which are yielding results are the many surveys which are financed by AMA funds and the scientific research programs which it encourages and frequently sponsors.

One important survey to which the AMA is lending constant support is the hospital survey provided for in the Hill-Burton Hospital Survey and Construction Act. The AMA has directly sponsored several surveys in order to promote the extension of medical care in rural communities. With the co-operation of state and county medical societies it has surveyed the medical facilities and medical personnel in every county in the United States and has made the information obtained available to all medical schools and to all hospitals approved for internships and residencies for the purpose of helping young physicians choose locations for practice.

A study of medical schools in 1947 revealed that many have preceptorships with rural physicians for medical students in their senior year, scholarships for students who will practice in rural areas and many other plans for interesting younger men in rural practice.

An interesting two-part study on the utilization of medical facilities and personnel during an emergency was recently carried out. Phase One investigated medical services on the home front. Questionnaires were sent to physicians who remained home during the war. (While sixty per cent of practicing physicians carried 91 per cent of the pre-war patient load, it was found that 1942, the first year of heavy inductions, was the healthiest in U.S. history, up to that time.) Results of the study will be used to determine how even better results may be obtained in the event of another national emergency. The second phase of the survey was conducted among the returned medical officers to determine how medical personnel was utilized by the armed services. The study summarizes opinions and constructive criticisms made by the nation's wartime medical officers. Results will be of value to the Department of National Defense in planning medical policies for future use in the entire national defense establishment in peace and in war.

Other surveys undertaken by the AMA include one on the cost of medical care, one on the distribution of physicians and supply of medical services and one on the implications of group practice.

AMA Has Testing Laboratory

One of the important services which the AMA performs for the direct benefit of the public and for which it is well known is the examination of foods, drugs and various other products and devices. It maintains a laboratory to test preparations submitted for consideration and places its famous seal of approval on those which meet its rigid standards.

Not only does the AMA carry out such tests but it also is concerned with the development of

new tests and standards by which products can be identified and controlled. Practically everything which the AMA does encourages research or the use of knowledge gained from research. Through its scientific publications the results of research are published. Current research projects are listed periodically in the *Quarterly Cumulative Index Medicus,* put out by the AMA. The Association has created three special committees which have medical research functions. One attempts to co-ordinate and arrange research projects and the others make available funds for research purposes. In 1947 the AMA established a trust fund of $1,500,000, the interest from which will be used each year to support medical research. In all of its activities, the AMA works to advance the health standards in this country. It is in the hope that American Medicine will always maintain its enviable record that the medical profession through its national organization guards jealously our system of freedom of enterprise, which is the only system under which medicine can hope to exist or advance.

COUNCIL APPOINTS COMMITTEE TO REVISE MSMA CONSTITUTION

At its December meeting, the Council of the Minnesota State Medical Association appointed a four-man committee to undertake a study of the Association's Constitution and By-Laws.

The old Constitution, adopted by the House of Delegates in 1937, is still basically sound; it lays down a set of fundamental principles which embody the ideals of medicine and medical organization. However, it has been brought to the Council's attention that certain difficulties and inconsistencies have been encountered which indicate that the Association has outgrown some of the methods employed in medical organization at the time the Constitution was first drafted. Therefore, it was decided that a careful examination should be made of the present framework to determine what practices are now outmoded and to decide where revisions should be made.

Appointed to undertake the project are Dr. O. J. Campbell, Minneapolis, who will serve as the chairman of the committee, Drs. C. B. Drake and B. B. Souster, St. Paul, with Mr. F. Manley Brist, Association attorney, as legal counsel. The group will study the present Constitution and By-Laws thoroughly, formulate the needed revisions and submit them to the House of Delegates for final approval.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
Saint Paul, Minnesota

Julian F. DuBois, M.D., Secretary

Minneapolis Man and Woman Sentenced for Criminal Abortion

Re. State of Minnesota vs. Vern E. Jorgensen and Lillian Mullane.

On February 5, 1948, Vern E. Jorgensen, thirty-five years of age, 4036 Zenith Avenue North, Minneapolis, and Mrs. Lillian Mullane, fifty years of age, 4407 Portland Avenue, Minneapolis, were sentenced by the Hon. Frank E. Reed, Judge of the District Court of Hennepin County, following their respective pleas of guilty on November 10, 1947, to an information charging them, jointly, with the crime of abortion. Jorgensen was sentenced to a term of not to exceed four years in the State Prison at Stillwater, the sentence being stayed and the defendant placed on probation for a period of five years. Mrs. Mullane was sentenced to a term of two to eight years in the Women's Reformatory at Shakopee, the sentence being stayed and the defendant placed on probation for five years, provided, however, that Mrs. Mullane must serve the first year of her sentence in the Minneapolis Women's Detention Home. Mrs. Mullane's sentence was doubled because of the fact that on October 8, 1924, she was convicted of grand larceny in the second degree in the District Court of McLeod County, Minnesota.

The defendant Jorgensen, who posed for several months in Minneapolis as "Dr. Vern Roberts," and the defendant Mullane, were arrested on a complaint issued October 18, 1947, in the Municipal Court of Minneapolis charging both, jointly, with performing a criminal abortion on a thirty-five-year-old married woman. The abortion was done by the defendant Jorgensen at the home of the defendant Mullane by means of a catheter. Jorgenson was paid $160 for his services. Jorgensen admitted that he had been posing as a doctor and that he had performed approximately 100 criminal abortions during the past three or four years. Jorgensen is a son of Mrs. Anna D. Huff, who on May 17, 1943, entered a plea of guilty in the District Court of Ramsey County to an information charging her with the crime of manslaughter following a criminal abortion. For that crime Mrs. Huff was sentenced to a term of five years in the Women's Reformatory at Shakopee, which sentence she served. The defendant Mullane has a long criminal record consisting of five convictions for shoplifting in Minneapolis and St. Paul. She also has two previous convictions for the illegal sale and possession of liquor, one in 1926 and one in 1929, in addition to the larceny conviction in the District Court of McLeod County.

The Minnesota State Board of Medical Examiners wishes to acknowledge the very fine co-operation received from the Minneapolis Police Department in the investigation of this case and from the Hennepin County Attorney's office in the presentation of the matter in Court. The Medical Board also believes that the sentence imposed by Judge Reed will convince the defendant Mullane that she cannot shift her operations from shoplifting to being an accomplice of an abortionist. Judge Reed warned the defendant Jorgensen that he was receiving probation because he did not have a previous conviction for a felony and that if any complaint is made about his activities during the next four years, and the facts support the complaint, Jorgensen would be taken to Stillwater to serve his entire sentence.

Minnesota Academy of Medicine

Meeting of October 8, 1947

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 8, 1947. Dinner was served at 7:00 o'clock, and the meeting was called to order at 8:00 p.m. by the president, Dr. E. M. Hammes.

There were fifty-five members present.

Dr. Carl B. Drake read the following memorial to Dr. William Davis, and a motion was carried that it be placed on the records of the Academy and a copy sent to the family of Dr. Davis.

WILLIAM DAVIS, 1853-1947

Dr. William Davis, the last surviving charter member of the Minnesota Academy of Medicine, passed away on May 9, 1947, at the age of ninety-three. He had practiced fifty-six years before his retirement on April 30, 1939.

Dr. Davis was born in Plymouth, Massachusetts, September 28, 1853, the ninth lineal descendant of his Pilgrim ancestors to be born in that historic town. He attended Phillips Exeter Academy before receiving his B.A. degree from Harvard College in 1876 and his M.D. from Harvard Medical School in 1879. He served a three months' internship at the McLean Lying-In Hospital in Boston and spent a year in Vienna in postgraduate study.

After practicing in Syracuse, New York, for three years, Dr. Davis moved to Saint Paul in 1883, the same year joining the Ramsey County Medical Society. He was president of his county society in 1892, president of the Minnesota State Medical Association in 1901, and a member of the Minnesota State Board of Medical Examiners from 1900 until 1906.

Dr. Davis was interested in early medical publications, having been editor of the *Northwestern Lancet* from October, 1886, until December, 1899, and on the Editing and Publishing Committee of the *Saint Paul Medical Journal* from 1901 until 1912.

The Minnesota Academy of Medicine was founded October 12, 1887. Dr. Davis' first paper before the Academy was on October 9, 1894, on the subject of "Movable Kidney." This was published in the *Northwestern Lancet* (vol. 14, p. 478). He was elected president of the Academy on October 7, 1903, and gave his presidential address the following month (as was then the custom) at the meeting of November 4, 1903, on "Unusual Sources of Poisoning." This contribution was published in the *Saint Paul Medical Journal* in 1904 (vol. 6, p. 34).

At the meeting of February 10, 1932, Dr. Davis presented to the Academy the original copy of the minutes of the first meeting of the Academy which were decorated with original drawings by Dr. E. C. Spencer of Saint Paul, who was then secretary, and the page was bound in the Proceedings of the Academy for that year.

Dr. Davis married Sally White Holyoke on June 26, 1878. They celebrated their golden wedding in 1928 at their summer home at South Orleans, Massachusetts, surrounded by family and friends. Mrs. Davis died in 1929. He is survived by four children, fourteen grandchildren and twenty-two great grandchildren, one grandson having been killed in World War II.

Dr. Davis built a summer home at South Orleans in 1907 and spent his summers there yearly until 1942. His summer home proved a Mecca for friends visiting in the East and was continuously filled with members of his family.

He was a member of Unity Church in Saint Paul and for many years belonged to the Informal Club. He was fond of bridge and played a keen game until he was invalided as a result of a fractured hip in November, 1945.

Dr. Davis was an esteemed member of the medical profession and of the Minnesota Academy of Medicine. His was a life rich in service and friends.

The scientific program followed.

Dr. Stanley Maxeiner, Minneapolis, read his inaugural thesis which follows. Colored motion pictures were shown.

THE TOURNIQUET AMPUTATION

STANLEY R. MAXEINER, M.D., F.A.C.S.
Clinical Associate Professor of Surgery, University of Minnesota
Minneapolis, Minnesota

Tourniquets have been applied for centuries for the control of hemorrhage. Heliodorus,[3] in the second century A.D., referred to its use in the control of bleeding during amputation of the extremities, and many types of tourniquets have since been devised to suit the purpose for which they were intended. In all of these applications, compression was used for the sole purpose of controlling bleeding until surgery could be instituted, either by ligation or amputation. We have found no record in the literature previous to 1924 of case reports in which the tourniquet was applied for the purpose of limiting infection. At that time R. E. Farr,[2] with whom I was associated, reported three cases before the Minnesota Academy of Medicine. One case of gas gangrene of his own and one of the writer's, so treated, survived almost overwhelming infection. The third patient, also similarly treated for virulent infection superimposed upon arteriosclerotic gangrene in the presence of cardiac decompensation, expired from cerebral thrombosis after five days. The extremities were wrapped in

Inaugural thesis.

formaldehyde solution distal to the tourniquet and encased in a rubber envelope.

We have now treated more than twenty patients by this method, which we have modified and improved from time to time. The first decision, and perhaps the most important one to be made, is that the damage to the extremity is irreparable and that it must be sacrificed. Secondly, in the very bad-risk patient in whom a primary classical amputation would probably be fatal, the tourniquet is applied as an expedient in the hope of saving life. Later, the second stage may be completed either according to our technique or, when the general condition of the patient will permit, by performing a classical amputation.

In 1924 the author started using as a tourniquet about 5 feet of one-half inch pure gum rubber tubing, which is stretched very tightly and remains tight as it cuts deeply into the tissues. Pain is usually minimal, as the pressure from the rubber tubing produces anesthesia of such degree that only moderate sedation is required.

Much has been written in recent years about refrigeration for anesthesia and for the preservation of tissue of impaired vitality. Refrigeration has been used with and without the tourniquet, but we have continued to use formaldehyde solution because of the simplicity of its use and the fact that when the part is encased in rubber the process is odorless. We have repeatedly cared for patients so treated in large wards. Recently we used our technique in a Sisters' hospital where the leg had been treated for days by refrigeration. The contrast was convincing when they no longer had to carry pails of ice and water.

The writer served in the armed forces in the first World War and is convinced that many lives could have been saved by the sacrifice of an extremity by the tourniquet technique. We have so treated several patients whose extremities, one or more, had been traumatized so severely that amputation was inevitable. It is truly amazing to observe the minimal systemic reaction, the absence of shock, and often the almost immediate improvement following the institution of this procedure. In 1941 I published an article on, "The Temporary Tourniquet Amputation"[4] in which I stated, "During a recent trip south I saw an article in the San Antonio paper to the effect that an airplane pilot had crashed and sustained such a mutilating injury to both legs that double amputation was necessary. The article further stated that the pilot promptly died following the shock of the accident and the operation." We firmly believe that in war or peace, and especially in industrial and traffic accidents, the tourniquet technique affords a temporary expedient, a procedure of minimal severity, at a time when definitive surgery would be hazardous. The tourniquet may be left on for days, and the rubber tubing will complete a guillotine operation without shock, or a secondary elective operation may be performed at an optimum time. Major Paul Adolph,[1] in an article entitled, "Preoperative Measures Used in War Surgery in China: With Special Reference to the Delimiting Tourniquet," states that they used the tourniquet to obtain preoperative improvement before amputation, in the severely toxic patient who may have been lying out on the battlefield for two to three days. The lives of Chinese soldiers, whose extremities were badly mutilated and infected, were saved when the delimiting tourniquet was employed.

Indications

There must be the necessity for an amputation as a life-saving procedure in the presence of forbidding surgical risk. These indications exist in the presence of (1) severe trauma with irreparable damage to an extremity of a patient who is suffering severe shock from the loss of blood or the magnitude of his injuries, (2) virulent infections, especially gas gangrene, and (3) gangrene due to diseased peripheral circulation with superimposed infection or concomitant diabetes or critical heart disease.

Necessary Equipment

Pure gum rubber tubing, five feet.
White cotton, sterile, one roll.
Dental rubber dam, sterile.
New rubber draw sheet, one.
Formaldehyde solution, 10 per cent, one gallon.
Roller bandage, 4-inch, one.

Technique

The procedure may be employed either in the operating room or in the patient's bed. The latter has been found to be a decided advantage in critically ill patients with gangrene complicating diabetes or heart disease. We have repeatedly found intravenous morphine or intravenous morphine and scopolamine to furnish adequate anesthesia. Likewise, pentothal sodium has been very satisfactory.

The skin of the extremity is first painted with antiseptic solution several inches above and below the site of application of the tourniquet. The dental rubber dam or a strip of pure gum rubber, 6 to 8 inches wide and long enough to encircle the extremity and overlap a few inches, is placed so that its lower border is at the site of amputation. Next, the rubber tubing is tightly stretched and wrapped about the site of amputation just including the lower border of the rubber dam. Each turn of the tubing overlaps the one below so that the constricted area is as narrow as possible. The ends of the tubing are secured by taping together firmly so that they cannot possibly slip. The extremity distal to the tourniquet is next wrapped with a goodly quantity of white cotton. It is well to use the cotton in abundance. The new rubber draw sheet is next applied so that the extremity may be securely enclosed. The cotton is next saturated with about two quarts of formaldehyde solution, and the closure in the rubber sheet is completed and held fast with the 4-inch bandage. The rubber dam is next turned distally, sealing the upper opening of the wrapped sheet, and held securely by a few laps of the bandage. By this means, the extremity below the tourniquet is preserved in a laboratory solution which renders the gangrenous part odorless, nor is there any odor from the formaldehyde. We have repeatedly cared for these patients in wards without complaint.

Postoperative Care

General supportive treatment may be carried out as usual. Transfusions and infusions may be used as desired, and likewise, antibiotics if indicated. There is no interference with the routine treatment for the patient's shock, his diabetes or his heart disease. Mild sedation is usually adequate since, in only a few hours, the gradual compression of the tourniquet produces pressure anesthesia. This feature has almost been the rule although one or two patients have required greater amounts of sedation.

Usually once daily the rubber envelope is opened slightly and one to two pints of formaldehyde added to assure against odor from the gangrenous part.

Secondary Procedures

After the tourniquet has been applied and supportive treatment instituted, the condition of the patient may improve to such a degree that the surgical risk is lessened. Two alternatives present:

1. A classical amputation may be done, with flaps fashioned above the tourniquet. This is particularly applicable to crushing injuries not accompanied by severe debilitating disease. Naturally, it is the more rapid and the more ideal method of producing a definitive stump in selected cases.

2. The continued action of the elastic rubber tubing for eight to ten days will compress a groove through all the soft tissues to the bone. There remains only a hard dry cuff over the bone, completely free of sensation. As a result, a Gigli wire saw may be placed in this groove immediately above the tourniquet and the remaining tissue and bone cut across without anesthesia. The result is a guillotine operation. Usually the skin edge and layer of muscle eventually separate due to the crushing. Occasionally, at this time we divide the bone several inches higher under local anesthesia and use adhesive traction to pull the soft tissues together. One may choose, however, to dress the stump aseptically and, at a later date, perform a plastic operation, removing adequate amounts of bone and muscle to permit the skin edges to be approximated loosely by through-and-through sutures. Though more time consuming, this latter procedure will permit the saving of life in a larger number of amputations complicated by sepsis and severe debilitating disease.

Mortality

This procedure is an expedient made available to the critically ill patient in whom the classical operation of choice would be too hazardous. The application of the tourniquet and dressings produce no shock. In no patient have we observed any direct adverse symptoms. No deaths, I believe, can be attributed directly to the procedure when followed as described. One death occurred during anesthesia for severing of the painless compressed bed of the tourniquet. Most deaths have been due to the debilitating disease from which the patient suffered. Some who survived are, we believe, definite salvage attributable to the method.

Early in our experience we always had another tourniquet ready for possible secondary hemorrhage, but none has ever occurred.

Statistics of the twenty cases reported indicate there have been six deaths, or a mortality of 30 per cent, and, as stated, none of them can be attributed to the method.

Case Reports

Cases 1 and 2 are briefs of two case reports by Dr. R. E. Farr before the Minnesota Academy of Medicine February 13, 1924, and published in the *Annals of Surgery*, 79:913-916, 1924.

Case 1.—Robert, aged sixteen, had his left arm run over by a truck on March 19, 1923. Two days later he was referred to Dr. R. E. Farr by Dr. E. S. Geist. The boy was in critical condition, with his temperature 102° and pulse 120. Hemoglobin was 28 per cent. He had a gas gangrene involving his whole arm and shoulder. Multiple incisions were made over the shoulder and a tourniquet applied to the arm. The patient recovered.

Case 2.—Mrs. S. K. was seen by Dr. Farr on June 6, 1923. She had had a cerebral accident and developed gangrene of the left lower extremity. Palliative treatment was of no avail, and a tourniquet was applied. Five days later the amputation was completed. Six days later the patient succumbed to a terminal cerebral accident.

Case 3.—A young male adult, while reaching across a circle saw, severed most of the tissues just distal to the axilla. When seen at the end of forty-eight hours he was in extremely critical condition; his temperature was 102°, his pulse 120, and practically the entire arm below the injury was infected with gas bacillus. The skin was dark, there were no pulsations and no sensation. The general condition of this patient was so critical that in the opinion of those who saw him, he would not stand a surgical amputation.

A tourniquet was placed as high up on the arm as possible and the distal arm wrapped in 10 per cent formaldehyde. Several areas over the shoulder which crepitated were incised and Dakin tubes were introduced. The patient soon began to improve, and his temperature and pulse fell to normal within a few days. One week after his entrance to the hospital, the condition of the patient was such that he was taken to the operating room, and it was found that the tourniquet had cut through all of the soft tissues and it was necessary for us to divide only the bone. At a subsequent date a plastic operation covered the denuded surfaces. The patient made an uneventful and rather rapid recovery.

Case 4.—Mr. E. E., aged fifty, fell head foremost beneath a train, and the wheels severed both arms at the elbow joints. When first seen by us, the patient was almost moribund with a blood pressure of 0/0. He was treated with oxygen, transfusion, stimulants, et cetera, and at the end of three and one-half hours his condition permitted a temporary surgical amputation of the right arm. He was given prophylactic tetanus and gas bacillus antitoxin. A tourniquet was wrapped around the left arm at the lowest point of viable tissue. Forty-eight hours later he had a rapid rise in temperature, a chill, and gas bacillus infection was found in the left arm above the tourniquet. The patient was again returned to the operating room and the left arm amputated surgically. Dakin tubes were introduced for his gas bacillus infection. Subsequent plastic operations were necessary on both arms, but he made a very satisfactory recovery.

At the time of the accident the patient survived one amputation with difficulty. The tourniquet permitted us

to delay operation on the other arm until his general condition permitted. Gas bacillus infection in the left arm certainly would not have occurred if, in our eagerness to conserve all possible tissue, we had not placed our tourniquet too low. During the second operation it was quite obvious that hemorrhage, muscle laceration, et cetera, had occurred proximal to the site of the tourniquet.

Case 5.—A male adult, aged seventy-eight, was struck by a truck, sustaining compound, comminuted fractures of the tibia and fibula and severance of the soft tissues of the calf of the leg, including the vessels, nerves and muscles. There was no sensation and no pulsation below the knee. The patient was taken to the General Hospital in severe shock where he was treated in the emergency room and given 750 c.c. of blood. He was subsequently moved to a private hospital where he entered our care. He was still in shock. His systolic blood pressure ranged from 80 to 90 but his skin was cold and his general condition was poor.

The original tourniquet was removed and an elastic rubber tube tourniquet wrapped about the leg at the level of the knee. The leg below the tourniquet was wrapped in 10 per cent formaldehyde and encased in a rubber sheet. The patient was given an additional 600 c.c. of blood, but his general condition was bad. Part of the time he could not be aroused and we felt that amputation at that time was definitely contraindicated. At the end of twenty-four hours his condition was greatly improved. His blood pressure was 140/70. The next day he was taken to the operating room, and under local anesthesia a mid-thigh amputation was performed. He was subsequently given several transfusions and other supportive treatment.

The patient had a rather stormy convalescence, but we were fortunate to have primary healing of his flaps. On the sixteenth postoperative day the patient developed bronchopneumonia from which he recovered, and he was discharged from the hospital on the twenty-sixth day with the flaps completely healed.

Case 6.—Mrs. S. H., aged fifty-eight, who was referred to us through the courtesy of Dr. W. K. Foster, had been a victim of arthritis and heart disease for a long period of time. On February 27, 1941, when seen by Dr. Foster, the patient gave a history of very severe pain in the left leg six days previously and a second attack with violently severe pain in the right leg three days previously.

On examination the popliteal vessels were found to be completely occluded with a beginning gangrene of the left foot and left leg. The right leg had undoubtedly started as a popliteal occlusion, but the thrombus had formed until it had occluded the deep femoral vessel, and gangrene had already extended well up onto the thigh. The patient was in extremely critical condition, with decompensation and auricular fibrillation and at times delirium.

She was treated medically for several days and was presented clinically to the Surgical Section of the American College of Surgeons meeting in Minneapolis as a problem case. We all agreed that inasmuch as the patient was improving and both legs were undergoing a dry gangrene, it was better to let the patient alone. However, a few days later she became progressively more toxic with elevation of temperature, and it was quite obvious that the right leg was the cause of her relapse. A piece of gum rubber tubing was wrapped tightly around the thigh at the lowest point at which the amputation might be considered successful. The distal leg was wrapped in formaldehyde dressings covered with rubber sheeting. At the end of nineteen days the patient was very greatly improved. The tourniquet had cut through all of the soft tissues and the bone was severed. The patient's condition improved materially during the time that the tourniquet was cutting through the thigh, and after the amputation, her temperature returned nearly to normal and her pulse and heart action were greatly improved. Surgical amputation on this patient at any time since we first saw her would have been fatal. However, she stood the tourniquet amputation without any apparent ill effect on her already critical condition. A tourniquet amputation of the other leg was contemplated.

In this case, because of the high thigh amputation and the possibility of secondary hemorrhage from the femoral artery, a sterile tray with Kirschner wires and tourniquet was maintained in constant readiness in the patient's room. The Kirschner wires naturally were to keep the tourniquet from slipping off when applied in such a high position.

NOTE: After publication of the preceding report, the patient's other leg was treated by the tourniquet method. On the sixth day, however, before the amputation was completed, she suddenly expired from a coronary occlusion.

Cases 3, 4, 5 and 6 have previously been reported.

Case 7.—Mrs. E. J., was seen in consultation with the late Dr. W. Moir. This patient, seventy-two years of age, entered Asbury Hospital on November 17, 1941. She had been a diabetic for years. For two months she had had a progressive gangrene of the left third and fourth toes. Blood sugar was 286 milligrams per cent.

On November 27, 1941, an amputation was done by Dr. Moir at the tarsometatarsal joints, removing the gangrenous area. Infection aggravated her condition, and her temperature rose to 103° on the third postoperative day. On the eleventh and twelfth postoperative days the patient was delirious. Temperature was 102° with very difficult control of sugar.

On the twelfth postoperative day a tourniquet was applied in the patient's bed and the leg wrapped in formaldehyde dressings. Twenty-four hours later her temperature was normal, she had lost her delirium, and the diabetes was more readily controlled.

Ten days after application of the tourniquet the leg was amputated. The bone was divided at a higher level and the skin edges loosely approximated. This patient recovered and returned home about three weeks later with the stump nearly healed.

Case 8.—Mr. K., aged sixty-eight, a married man, gave a long history of cardiac disease. His heart had been irregular for years. On February 18, 1944, he stated that he had had a mild stroke two years previously. During the past year he had been better and had worked daily. On the morning of February 18 when he got up, he began to have numbness in his right foot, then blanching and severe pain. He was hospitalized, and an iliac embolectomy was done by Dr. H. Hoffert and myself with complete recovery.

The patient developed the same symptoms, with pain, numbness and a cold right leg, on September 24, 1945. He was seen late by Dr. A. Cardle, who stated his heart was fibrillating and his condition was not good. When seen by me, he had a gangrene of his right leg. An electrocardiogram was reported to indicate the presence of (1) auricular flutter, (2) myocardial damage, (3) left axis deviation and (4) coronary disease.

On September 28, 1945, the patient's condition was not good, and he was complaining of very severe pain in his right leg. A rubber tourniquet was applied and the leg wrapped in formalin. During the next two days the patient had almost no reaction and required only two hypodermics for pain during the first twenty-four hours. Nine days postoperatively, his condition had improved to such a degree that he was taken to the operating room and the amputation was completed by Dr. Hoffert. The bone was divided at a higher level and adhesive traction brought the skin edges togther. Thirteen days later he was discharged from the hospital with the

stump partially healed. He was subsequently fitted with an artificial limb.

Case 9.—Mrs. D., aged seventy-three, entered St. Mary's Hospital on September 14, 1943. The history and physical examination revealed hypertension, left heart failure and severe diabetes. She had a gangrenous left foot which produced a severely toxic effect. Her electrocardiogram was normal, but the x-ray revealed cardiac enlargement and pulmonary congestion. Sixty-five units of insulin failed to keep her urine sugar below 3 to 4 plus. She developed a severe infection, rapidly spreading into the gangrenous foot, and her temperature rose to 102° plus.

On September 21, 1943, a tourniquet was applied below the knee and the distal segment wrapped in formalin, encased in a rubber sheet. On September 22, 1943, twenty-four hours later, her temperature was normal, she had no shock or ill effect and almost no pain from the application of the tourniquet. Nine days later the amputation was completed with a Gigli saw without anesthesia. There was more slough at the end of the guillotine stump than usual and one week later, when the patient's condition permitted, she was taken to the operating room and, under local anesthesia, the bones were divided at a higher level and skin flaps fashioned and loosely approximated. The patient recovered slowly and returned home with the stump nearly healed.

Case 10.—Mrs. J., reported through the courtesy of Dr. L. K. Buzzelle, was an elderly lady who had a severe heart attack in California. Several weeks later she was removed from a train in Minneapolis and taken to Asbury Hospital in a semiconscious state. She developed an embolic gangrene of the left leg and was in very critical condition. Because of her severely toxic condition, amputation was advised, and because of her critical state, a tourniquet amputation was selected as the least hazardous.

A tourniquet was applied June 15, 1945, and the leg wrapped as usual. There was no shock or deleterious effect from the procedure and on the tenth postoperative day the amputation was completed. Traction was used on the skin of the stump. She weathered her operation without event but, five days later, had a hemiplegia from which she expired. Autopsy revealed coronary sclerosis, arteriosclerosis, hypertensive kidney disease, and the immediate cause of death to be cerebral hemorrhage.

Case 11.—Mrs. C. was seen in consultation with the late Dr. Salt.

This patient, forty-nine years of age, married, was seen by me when she was in a pitiful state. She had sustained a fracture of the right hip which was treated by open operation and mechanical fixation with evident success. Subsequently it became necessary to remove the screws, and the wound later became infected. She developed an osteomyelitis with destruction of the neck and upper shaft of the femur. When seen by me, the patient was a confirmed drug addict who cried out upon the slightest manipulation. Her leg was frail and turned if not supported. Nursing care was a problem as she ate little and had fallen away badly in weight. It was almost impossible to turn her or care for her.

Amputation was advised but none believed she could tolerate an operation of election. As a result, a tourniquet was applied under pentothal sodium at a level 3 inches below the greater tuberosity on March 20, 1945. She had a stormy time for several days, but sixteen days later, under the influence of morphine sulphate, the amputation was completed in the patient's bed. The leg healed slowly, and two months later she was discharged from the hospital. The stump was nearly healed, and she was no longer taking any drugs. She was eating well and had gained weight.

Case 12.—Mr. F., aged fifty-seven, a married man, stated that he had had diabetes for nine years which was controlled by diet. He had developed a sore on the outer side of his right foot three years previously which responded but little to treatment. Three weeks before he was seen, the foot became progressively worse with swelling and discoloration, and a moist gangrene involved the foot.

When seen by us, he had a swollen, moist gangrenous foot with streaks extending well up the leg. On January 13, 1946, his temperature was 101° and pulse 100. Urine revealed sugar, 4 plus; his blood sugar was 258 mg. per cent, and white blood count was 33,000. The next day his condition was worse, and his temperature rose to 102°. At that time the first stage of a tourniquet amputation was instituted. At the end of twenty-four hours his temperature was normal, pulse 75 to 80, and the sugar in his urine was 2 plus. He required only one hypodermic in the first twenty-four hours, and one daily controlled pain during the first few days.

Ten days later the patient's condition was excellent, and a Gritti-Stokes operation was performed. There was little reaction to either operation and the patient was discharged sixteen days later with primary healing.

Case 13.—Mr. J. McM., aged sixty-one, was admitted to the hospital quite toxic and incoherent. We obtained information that he had a painful foot for six weeks, but he continued to work on a farm. During the past week the middle toe of the right foot became black, and the pain was so great that he could not be up and about. When seen by me, he was very toxic, confused mentally and complained of intolerable pain in his foot and leg. He presented a swollen right leg with a typical picture of moist gangrene extending to just below the right knee. Cellulitis was starting up the thigh. His blood sugar was 188 mg. per cent but he had 3 plus sugar in his urine.

On December 31, 1947, the first stage of a mid-thigh tourniquet amputation was performed. He experienced no shock and no noticeable ill effect. His blood pressure remained 120/60 throughout. Six days later the amputation was completed without anesthesia and a sterile dressing applied over a guillotine stump. One week later when the patient was up in a wheel-chair he suddenly expired from coronary occlusion.

Case 14.—Mrs. K., a middle-aged woman who was in excellent condition, was skillfully operated upon by another surgeon for a fibromyoma of the uterus. Four days later she developed severe pain in her right leg with blanching, numbness, reduced temperature and an absent pulsation in the arteries of her foot. An embolectomy was done, but gangrene developed. Two days later a guillotine amputation was done 6 inches below the knee where the circulation seemed good. The stump became septic and the flaps sloughed. She had chills and severe reactions from all transfusions, and one month after the embolectomy she became delirious, with temperature to 103° and pulse 140. He condition was so serious that she undoubtedly could not have stood a surgical mid-thigh amputation.

A rubber tube tourniquet was applied, and the temperature fell and delirium improved. However, she continued to have pain, and her condition remained poor, so that when her temperature again rose to 102° she was taken to the operating room and, under general anesthesia, a guillotine amputation completed. Although her convalescence was stormy and slow, she made a complete recovery. I believe in this instance the tourniquet delayed amputation and improved her general condition enough to permit a successful guillotine operation.

Case 15.—This patient, a man, aged seventy-five, entered the University of Minnesota Hospitals in very poor condition. He was completely studied, and unrelated

findings will not be reported. His hospital diagnoses were (1) diabetes, (2) arteriosclerosis, (3) coronary heart disease and (4) gangrene of left leg. The patient complained bitterly of pain in the gangrenous leg; his temperature was moderately elevated, and there was mild sepsis.

Morphine and scopolamine were given intravenously; a tourniquet was applied and the leg wrapped in formalin. There were no unusual reactions but the patient's temperature remained elevated and the x-ray suggested the possible cause to be pulmonary. During the completion of the second stage under anesthesia, the patient expired. the autopsy revealed as the immediate cause of death, acute pulmonary atelectasis.

NOTE: The reports of Cases 16 and 17 are through the courtesy of Dr. R. Pogue, Watertown, Minnesota.

Case 16.—This elderly, very frail woman, aged seventy-five, a severe diabetic, developed gangrene of her left foot. She suffered severely for a long time and was confined to her bed because her family objected to amputation. She became moderately septic, with sugar, 4 plus, in her urine, and was controlled with difficulty by insulin. I do not believe an elective mid-thigh amputation could have been done successfully on this poor-risk patient. As a result a tourniquet was applied; there was no reaction, and her insulin requirement dropped instantly. Ten days later her condition was greatly improved and the second stage was done under local anesthesia, dividing the bone at a higher level and bringing the skin loosely together. She had excellent healing and made a splendid recovery.

Case 17.—This patient, a man, sixty-eight years of age, in January, 1947, complained of severe pain in his left foot where he had developed two ulcers. The patient was a severe diabetic with 4-plus sugar in his urine, poorly controlled with large doses of insulin. The infection progressed, and his temperature rose to 102°. On February 20, 1947, a rubber tube tourniquet was applied 6 inches below the knee and the leg wrapped in a rubber pillow filled with chopped ice. Almost immediately his temperature returned to normal, and the insulin requirement was cut one-half. Eleven days later, after an intravenous dose of morphine, the leg was severed with a Gigli saw. Insulin was discontinued and the patient experienced an uneventful recovery.

Of unusual interest in this case was the fact that Dr. Pogue was away, and instructions were given over long distance telephone to his associate who had never seen the method employed.

Case 18.—Mr. L. B., seventy years of age, married, was a printer by trade. He entered the hospital because of unbearable pain in his left foot and leg. He stated that he had had repeated anginal attacks since 1942, and one and one-half years later suffered a right hemiplegia. His hospital diagnoses were (1) arteriosclerotic heart disease, severe, (2) thrombosis of left femoral artery, (3) dry gangrene of left heel and toes of left foot, and (4) hemiplegia, right, secondary to cerebral embolism.

On January 31, 1947, under morphine and scopolamine given intravenously, a rubber tube tourniquet was applied. His temperature remained elevated and he expired four days later. Autopsy revealed (1) bronchopneumonia, (2) coronary sclerosis, generalized, (3) arteriosclerosis, generalized.

Case 19.—(By courtesy of Dr. W. White) This man, aged seventy-eight, had suffered from (1) arteriosclerosis, generalized, and (2) coronary arteriosclerosis and senility. He developed an acute coronary occlusion and was bed-fast. He fell out of bed and injured his left leg, which was followed by numbness in the leg for several days, when he developed an acute gangrene with very severe pain. It was because of the progressive condition of the disease and almost intolerable pain that amputation was advised.

A rubber tube turniquet was applied just above the knee. Eight days later the amputation was completed. The patient lived five days longer and expired in a state of general exhaustion and loss of strength.

Case 20.—This is probably one of the outstanding cases of this series and proves the value of the method in trauma.

The patient, aged sixty-five, a merchant, was crossing the railway tracks to his place of business when he was hit by a locomotive engine. He was taken to the Minneapolis General Hospital in severe shock, where he was given 750 c.c. of pooled plasma. He was then transferred to Asbury Hospital where he entered our care. Examination revealed the following injuries:

1. Crushing of the right foot with extreme mutilation of the tarsal and metatarsal bones.
2. Dislocation with compounded injury of the left ankle.
3. Fracture of the right pubic ramus, of the right ilium and separation of the right sacroiliac.
4. Fracture of the neck of the left femur.
5. Fracture of the transverse processes of the third and fourth lumbar vertebrae.
6. Fracture of the fifth, sixth and seventh ribs on the left and the sixth and seventh ribs on the right side.

Plasma and blood transfusions were administered, together with other supportive measures, and, as soon as his condition would permit, a debridement of the left ankle was done. The ankle joint, which was widely open, was freely irrigated. The dislocation was reduced and the wound closed with only a small drain. To maintain reduction of the ankle and at the same time keep the fractured femoral neck from displacing, a Kirschner wire was passed through the left os calcis and traction applied. We were convinced that surgical amputation of the irreparable right leg might well result fatally in one so severely injured. We applied a rubber tube tourniquet about the junction of the lower and middle thirds of the calf and wrapped the distal portion in a formalin dressing in a rubber sheet.

The patient responded well to supportive treatment, and on the eighth day the leg was severed with a Gigli saw without anesthesia. Eleven days later he developed a severe thrombophlebitis involving the left leg. Ten days after the onset of the phlebitis, we did an open reduction of the left hip and anchored the fractured ends with three large screws.

One month after the injury, the left ankle was healed, the right hip had been secured by internal fixation, and the guillotine stump of the right leg was healing well. One hundred days after the administration of the pooled plasma, he developed acute infectious jaundice. The guillotine stump was eventually closed by a minor plastic operation under local anesthesia.

It is now one year since the accident; the patient is quite well and wears a well-fitting artificial leg. The left hip is also firmly united.

NOTE: Since writing this paper, I have obtained a report from the Minneapolis General Hospital, through the courtesy of Dr. E. A. Regnier, in which the tourniquet was applied in twenty cases with sixteen deaths, or a mortality of 80 per cent. The high mortality rate is due to the fact that the tourniquet operation was used only in almost moribund cases who would tolerate only ice anesthesia and in whom general or spinal anesthesia were definitely contraindicated. The report also con-

cludes, however, that in no case could death be attributed to the use of the tourniquet.

Conclusions

The tourniquet amputation is an expedient to be used for those patients in whom an extremity must be sacrificed but in whom a classical amputation would be extremely hazardous in the presence of forbidding surgical risk. The tourniquet may be used for only a few days, at which time a classical operation may be done if the improvement in the patient's physical state warrants, or it may be allowed to remain on until a guillotine amputation has been accomplished, except that it is necessary only to divide the insensitive, compressed tissue and bone. The odor from the gangrenous extremity is prevented by the use of formaldehyde solution. We are convinced by our own experience that lives have been saved which might otherwise have been lost.

Discussion

Dr. A. A. Zierold, Minneapolis: I had understood that Dr. Regnier was to discuss this paper, and in his absence I have not had an opportunity to review his material. It is my recollection that several years ago we asked Dr. Maxeiner to come to the General Hospital, where he is a consulting surgeon, to demonstrate this procedure, and that we have used it since that time with a great deal of satisfaction. There is no question but that Dr. Maxeiner has added to our surgical development by this technique.

Some years ago, Cannon, in his studies on shock, demonstrated the value and danger of the tourniquet. If a tourniquet was applied to an extremity and the extremity was traumatized, shock did not develop; but if, after trauma to the extremity, the tourniquet was removed, shock promptly developed. Following Dr. Maxeiner's procedure, it should be possible, in similar cases in which amputation is contemplated, to apply a tourniquet at such a time as to prevent the shock which so frequently occurs following emergency surgery. I do not believe that there can be any quarrel with this technique and this procedure. It seems to be very reasonable. At the Minneapolis General Hospital we have used this method in individuals who had sustained injuries to the extremities and later developed infections which jeopardized the life of the individual, and the results have been very gratifying. We have not extended its use to the treatment of diabetic gangrene or to gas gangrene, but I believe we shall do so in the future. It is particularly interesting to note the results that Dr. Maxeiner cites in cases of gas gangrene treated by a tourniquet. Without this evidence, I should hesitate to use this method. I believe this technique will in many cases displace refrigeration anesthesia. Certainly it is quite as effective and much less trying to the patient and the hospital staff. I believe that we should be congratulated upon our opportunity to hear so new and so satisfactory a technique as Dr. Maxeiner has described.

Dr. H. B. Zimmermann, St. Paul: I have had absolutely no experience with Dr. Maxeiner's technique, but it seems entirely reasonable to me, and, if the occasion arises, I intend to use it. I was interested in his use of formaldehyde. I was at one time House Officer at General Memorial Hospital, in New York, and the patients with malignancy who were sent to the cancer hospital usually had very far advanced involvement. It was the custom there to do just as Dr. Maxeiner did, placing dressings of formaldehyde over the ulcerating lesion, even injecting the formalin with a needle right into the breast. Apparently it did no harm, and the patients improved after the treatment. The breasts dried up and were easily amputated. I have done that in cases of advanced and ulcerating malignant disease.

Dr. Donald McCarthy, Minneapolis: Those persons treated by this method whom I have seen have done very satisfactorily, and there has been lessening of the toxemia almost immediately upon the application of the tourniquet.

Dr. Maxeiner (in closing): I appreciate Dr. Zierold's kind remarks and realize that this is not a much used procedure. My idea in bringing it forth again is to endeavor to bring to the attention of the profession a procedure which we believe has great value in a certain group of patients who are critically ill. It is not an operation of election but one rather of desperation.

The meeting adjourned.

A. E. Cardle, M.D., *Secretary*

MINNEAPOLIS HEALTH STATISTICS

(Continued from Page 177)

pected cases already under observation an increase in the number of reported cases of tuberculosis in 1948 compared to average years is expected.

It is to be emphasized that these increases in reported cases does not mean that tuberculosis is more prevalent but rather that more unknown and unsuspected tuberculosis in apparently healthy people is being found and reported to the health department.

Real progress in venereal disease control was achieved during the year with a reduction in syphilis cases from 737 to 590 in 1946 and 1947, respectively, and a decrease in gonorrhea cases from 1,018 to 808 in 1946 and 1947, respectively.

No cases of smallpox, leprosy, or tularemia were reported during the year. Only one case of typhoid fever was reported.

The health agencies of the city, including the general public, worked together admirably during the past year. Under many handicaps, the hospitals, the physicians and the nurses of the community have performed a great service. As a result, Minneapolis has maintained the enviable position in the forefront of the large cities as a healthful place in which to live.

OPPORTUNITIES IN OVERSEAS PRACTICE

The U. S. Army Medical Department announces the availability of opportunities for advanced training and experience in the various special fields of medicine and surgery in overseas Army hospitals in Germany and Austria. These hospitals are registered with the AMA, and credit is given time spent in assignments to the specialties in them by the various specialty Boards. Eligible physicians should communicate with the Surgeon General, U. S. Army, Washington 25, D. C.

Minneapolis Surgical Society

Meeting of October 2, 1947

Dr. Thomas J. Kinsella, Presiding

THE SPHINCTER OF ODDI IN MAN

GEORGE S. BERGH, M.D.

Minneapolis, Minnesota

The discharge of bile into the duodenum is dependent upon the pressure of bile secretion, the activity of the gall bladder, and the tonus of the sphincter of the bile duct. Although attention has been directed to the biliary tract since antiquity, accurate knowledge of the sphincter of Oddi has been acquired only relatively recently.[3]

Anatomical Considerations

It has been established that there is a distinct sphincter at the terminal portion of the bile duct, and that this muscle develops independently of the duodenal musculature.[8]

As the bile and pancreatic ducts enter the duodenal wall they pass through a lengthwise hiatus in the longitudinal muscle and a transverse fenestra in the circular muscle. Boyden[14] has classified the muscles of the choledocho-duodenal junction into (1) muscles of the choledocho-duodenal aperture, and (2) intrinsic muscles of the ducts and ampulla.

The muscles of the choledocho-duodenal aperture include: (1) the superior and inferior margins of the choledochal fenestra, which impinge upon the ducts at only one level and differ in this respect from the anatomical arrangement in animals such as the dog; (2) reinforcing fibres (R-fibres) at the angles of the fenestra; and (3) connecting fibres (C-fibres) which secure the margins of the hiatus and fenestra to the papilla and ducts.

The intrinsic muscles of the ducts and ampulla include: (1) the sphincter choledochus, (2) the longitudinal fascicles, (3) the sphincter pancreaticus, and (4) the sphincter ampullae.

The sphincter choledochus is the most highly developed portion of the intrinsic sphincter of Oddi. It consists of an annular sheath of muscle fibres surrounding the bile duct from a position just outside the window to the junction with the pancreatic duct. It is capable of obstructing the flow of bile without closing the pancreatic duct. The sphincter pancreaticus is an annular band of fibres around the lower end of the pancreatic duct. It is not constant. The sphincter ampullae surrounds the ampulla, when the latter structure is present, and also encircles the lower end of the bile and pancreatic ducts. Kreilkamp and Boyden[14] found it to be well developed in only one-sixth of adults. Contraction of this muscle prevents the flow of bile and pancreatic juice into the duodenum and may permit the reflux of bile into the pancreatic duct or of pancreatic juice into the bile duct. The longitudinal fascicles consist of two columns of longitudinal fibres lying between the choledochus and the pancreatic duct. They probably serve to erect the papilla and facilitate the discharge of bile.

Physiological Considerations

There are marked species differences between the sphincter of Oddi of man and that of the common laboratory animals. On the basis of structural differences, anatomists have correctly predicted that the activity of the human sphincter would differ from that of animals. Boyden[7] has pointed out that, in man, the window in the duodenal muscle through which the bile and pancreatic ducts enter the intestine is of such shape and size that duodenal peristalsis exerts a minimal effect on the flow of bile. By contrast, the duodenal window of the dog has the shape of a funnel which envelops the first two-fifths of the intramural course of the bile duct. Most observers agree that, in animals, duodenal motility and tone exert a powerful influence on the flow of bile into the duodenum. But these factors are less important in man. Furthermore, it has been demonstrated[5] that the human sphincter of Oddi functions independently of the duodenal musculature. When we speak of the sphincter in a physiological sense, however, we may refer to the entire intramural regulatory mechanism, including both the action of the true sphincter and any influence which might be exerted by the muscle of the intestine.

The first activity to be attributed to the sphincter mechanism is the prevention of regurgitation of duodenal contents into the common bile duct, although the mucosal folds arising in the ampulla may be even more important in accomplishing this. When the sphincter action is eliminated, such as occurs in cases of internal biliary fistula, some degree of ascending infection follows. This infection usually is subclinical, but occasionally it may be severe. For this reason, Paine[18] has emphasized the importance of preserving the sphincter of Oddi whenever possible in reconstructive operations for stricture of the bile ducts.

A second function of the sphincter is to regulate the flow of bile into the intestine. Although bile is secreted continuously it is admitted to the duodenum only intermittently, depending upon the state of contraction of the gall bladder and of the sphincter of the bile duct.

A third function of the sphincter of Oddi is to aid in filling the gall bladder. If the sphincter mechanism be destroyed, the gall bladder does not fill and the bile flows directly into the intestine. If concentrated gallbladder bile has any superiority over unconcentrated hepatic bile in the process of digestion, the part played

Inaugural thesis.

in the filling of the gall bladder is an important function of the sphincter of Oddi.

A fourth function, attributed to joint action of the longitudinal fascicles and the connecting fibres, is to erect the papilla and facilitate the discharge of bile into the duodenum.

The extent of nervous control of the sphincter of Oddi still is not settled. The so-called Doyon-Meltzer law of reciprocal innervation of the gall bladder and sphincter maintains that when the gall bladder contracts, the sphincter relaxes as a result of reflex excitation. Apparently a reciprocal relationship actually does exist, at least under certain circumstances, but there is no good evidence that it is under nervous control in man. There is evidence, on the other hand, suggesting that the hormone, cholecystokinin, which causes the gall bladder to contract also produces relaxation of the sphincter of Oddi. Painful sensations identical with biliary colic may be produced by spastic contraction of the sphincter of Oddi in man.[4,15] The pain in some cases remains localized in the epigastrium or right hypochondrium, while in other cases there is radiation to the interscapular or right subscapular region. Associated with the pain, there may be abdominal muscle spasm and inspiratory distress, and occasionally nausea and vomiting. Schrager and Ivy[20] have demonstrated that in animals similar pain responses may be abolished by splanchnic section, and nausea and vomiting may be abolished by section of the vagi. It has been assumed that the sensory innervation of the sphincter in man is similar. Snell, McGowan and Butsch[21] have reported three patients upon whom right splanchnic section was undertaken in an attempt to relieve postcholecystectomy pain. The procedure was successful in one case. Experimental work of Boyden and Johnson[13] indicates that the lesser splanchnics and first lumbar roots of the celiac plexus may also participate in the conduction of pain impulses from the sphincter of Oddi.

Sphincter Resistance

The force which is exerted by the sphincter mechanism resisting the flow of fluid from the bile duct into the duodenum may be measured in patients with intubation of the common bile duct. Although sphincter resistance cannot be determined in entirely normal individuals, we have considered the measurements obtained in cholecystectomized and choledochostomized patients who had recovered from their operation, who were feeling well, and who had fasted for eight hours, as "normal." In such cases the sphincter can withstand pressures between 9 and 23 centimeters of water, and the sphincter resistance is most often around 12 to 15 centimeters. Changes of a few millimeters in the intraductal pressure occur during respiration, and marked changes are apparent during coughing, laughing or vomiting as a result of temporarily increased intra-abdominal pressure.

In some patients with choledocholithiasis, the sphincter may be irritable and may remain irritable for weeks or months after choledocholithotomy. In such cases the muscle readily goes into spasm and the intramural resistance may reach 30 or 40 centimeters of water or more, and usually fluctuates through a wide range instead of becoming stabilized. Such irritability probably is due to an inflammatory lesion—choledochitis secondary to stone. After several months of external drainage of the duct, the irritability disappears and the sphincter apparently returns to normal. These observations have led us to utilize sphincter resistance tests as one of the criteria for the determination of the proper time for removal of choledochostomy tubes.[3] The drainage tube is not withdrawn until the sphincter resistance is normal and examination reveals that the muscle is not irritable.

To hasten the return of the sphincter to normal, Macdonald[16] has advocated the use of postoperative perfusion of the biliary duct system with warm saline solution. If such irrigations are carried out, pressures only slightly above the sphincter resistance should be used. Forceful irrigations not only produce pain, but also may cause a recrudescence of an existing choledochitis with fever, general malaise, and sometimes even jaundice.

Mixer and Rigler[17] have shown that only moderate elevation of intraductal pressures may cause regurgitation of bacteria from the bile ducts into the blood stream. Diodrast or thorotrast, introduced into the ducts for purposes of cholangiography, likewise may be regurgitated into the blood stream if they are injected under pressure.

Hypertrophy of the sphincter muscle may occur in patients with an irritable sphincter, and several procedures have been suggested to combat such a condition. The most common procedure is gentle dilatation by the passage of graduated sounds at the time of operation. Any such instrumentation must be carried out gently to avoid tearing of tissues with subsequent scar formation. Colp and Doubilet[9] have advocated actual section of the sphincter with a special instrument which they have designed.

Response of the Sphincter to Food

It is well known that the ingestion of a meal is followed by a flow of bile into the intestine. Studies concerning the effect of various foods upon the activity of the sphincter of Oddi have demonstrated that ingestion of a fatty meal consisting of egg yolks and cream causes relaxation,[2] proteins occasionally produce relaxation, but neither a carbohydrate meal nor glucose given intravenously has any significant effect. Water taken by mouth also fails to produce a change in sphincter resistance.

Response of the Sphincter to Drugs

Morphine, codeine, pantopon and dilaudid produce prompt and prolonged contraction of the sphincter of Oddi.[3] In spite of that effect they are useful for the relief of biliary colic because of their central effect in the relief of pain. Utendorfer[22] has accumulated data which indicate that demerol also produces central relief from the pain of biliary colic without producing spasm of the sphincter of Oddi.

Amyl nitrite and nitroglycerine produce relaxation of the sphincter, but erythrol tetranitrate is ineffective. Trasentin, epinephrine, ephedrine, histamine and ethyl

alcohol sometimes produce sphincter relaxation, but the effects are inconstant.[3]

Magnesium sulfate[6] may produce sphincter relaxation with or without an initial contraction; it may produce an initial contraction followed by a return to the original tonus level, or there may be no effect. Relaxation, when it does occur, usually is not great, and contraction of the gall bladder following administration of magnesium sulfate probably is more important than sphincter relaxation in producing a flow of bile into the duodenum in patients with a functioning gall bladder.

Although atropine[1] does produce sphincter relaxation in the dog, it does not have any significant action upon the sphincter of Oddi in man, even in doses up to one-fiftieth of a grain. Pilocarpine, papaverine, posterior pituitary extract, benzedrine, prostigmine and caffeine sodium benzoate likewise have no significant effect upon the sphincter. The effects of sodium dehydrocholate, histamine, epinephrine, ephedrine, calcium gluconate and calcium chloride are not constant.[3]

Biliary Dyskinesia

As early as 1761, Morgagni suspected that spasm of the bile duct might produce clinical disorders. Oddi, with his more complete understanding of the anatomical arrangement of the muscular sphincter of the duct, advanced that proposition. More recently the importance of sphincter spasm in its relation to symptoms has been emphasized by many investigators. Ivy, Voegtlin and Greengard[12] have shown that motor dysfunction may cause biliary colic in normal human subjects with non-inflamed biliary passages. Observations made upon patients with choledochostomies also demonstrate clearly that spasm of the sphincter can produce pain. Pavel[19] has reported cases of functional obstruction with jaundice.

Presumably, therefore, a purely functional derangement (biliary dyskinesia or biliary dyssynergia) may produce spasm of the sphincter of Oddi with resultant biliary colic. In most instances, however, irritability of the sphincter is probably on an organis basis. Snell, McGowan and Butsch[21] have suggested that local inflammatory processes may induce sphincter spasm, and Ivy and Goldman[11] have pointed out that inflammation of the ampulla could make the muscle hyperirritable. Reflex contractions of the sphincter secondary to disturbances in more remote organs have not been demonstrated in man.

Sudden distention of the bile ducts produces deep epigastric or right upper quadrant distress. Gradual distention, on the other hand, produces no pain. The pain due to distention is less severe than pain due to sphincter spasm, and it is of a different character. Distention produces a dull distress, while sphincter spasm produces a sharper pain typical of biliary colic. In this connection it must be remembered that sudden distention of the bile ducts may cause the sphincter to go into spasm.

Ivy[10] has pointed out that a spastic sphincter can exert a resistance to flow greater than the force exerted by maximal gall-bladder contraction. Therefore, if the gall bladder contracts rapidly against a spastic sphincter, a sudden distention of the bile ducts occurs. Such conditions could lead to pain.[10]

Clinical diagnosis of biliary dyskinesia is extremely difficult. Symptoms may be ascribed to a functional disorder only after every effort has been made to rule out the presence of an organic lesion. Ivy[10] suggests that occasionally one may secure circumstantial evidence in support of the diagnosis. If the typical pain can be reproduced by administration of a fatty meal, cholecystographic studies should be carried out. Visualization of the cystic and common bile ducts after administration of a fatty meal is not unusual. But visualization of the hepatic ducts indicates that the gall bladder is expelling concentrated bile faster than the bile enters the intestine. Pain may result from spasm of the sphincter or distention of the ducts. However, more often the patients do not complain of pain, even though the hepatic ducts may be visualized during cholecystography.[10] Furthermore, negative cholecystographic studies do not entirely eliminate the possible existence of an organic disease.

Delayed evacuation of the gall bladder during cholecystography is not sufficient evidence for a diagnosis of dyskinesia, since the normal variation is great.[10]

Effect of Cholecystectomy upon the Sphincter

Since the time of Oddi, a number of investigators have recognized that extirpation of the gall bladder in certain animals, such as the dog, cat, and goat, and also in man, may be followed by dilatation of the biliary ducts. Several explanations have been advanced to account for this change. The most widely accepted explanation is that the dilatation is the result of increased intraductal pressure following cholecystectomy. This theory depends upon a persistence of action of the sphincter of Oddi. In the absence of the gall bladder, which normally acts as a pressure regulator, the increased pressure must be accommodated by dilatation of the duct. Our observations, and those of other investigators, support this view.[3]

Whether tone or response of the sphincter in man is altered by cholecystectomy cannot be stated definitely, since all studies have been made in individuals who have been operated upon. However, measurements of sphincter resistance in patients with choledochostomy tubes indicate that the sphincter does maintain tonus and activity following cholecystectomy, and the figures obtained are similar in range to those found in normal dogs.

In some cases the sphincter may exert abnormally high resistance to bile flow and may show irritability and go into spasm. A spastic sphincter may be one of the causes of postcholecystectomy colic.

Summary

The intrinsic sphincter of the common bile duct is anatomically and physiologically distinct from the duodenal musculature.

Functions which have been attributed to the sphincter of Oddi are: (1) making possible the filling of the gall bladder, (2) preventing the regurgitation of intestinal contents into the bile duct, (3) regulating the discharge of bile into the duodenum, and (4) erecting the papilla.

The force which is exerted by the sphincter mechan-

ism resisting the flow of fluid from the bile duct into the duodenum may be measured in patients with intubation of the common bile duct. Normal sphincter resistance varies between 9 and 23 centimeters of water, and usually it is around 12 to 15 centimeters of water.

In some patients with choledocholithiasis the sphincter may be irritable, and may remain irritable for weeks or months after choledocholithotomy. After prolonged external drainage of the bile duct, the irritability usually disappears and the sphincter returns to normal.

Any substances injected into the bile ducts for treatment or diagnosis (e.g., cholangiography) should be injected gently. Only moderate elevation of intraductal pressure may cause regurgitation of bacteria into the blood stream. Forceful irrigations may also cause a recrudescence of an existing choledochitis with fever, general malaise, and sometimes even jaundice.

The ingestion of a fatty meal causes relaxation of the sphincter, proteins occasionally produce relaxation, but neither a carbohydrate meal nor glucose given intravenously has any significant effect.

Morphine, codeine, pantopon and dilaudid produce contraction of the sphincter of Oddi. Demerol does not cause spasm of the sphincter.

Amyl nitrite and nitroglycerine produce relaxation of the sphincter.

The sphincter of Oddi is of clinical significance. Purely functional derangements may produce spasm of the sphincter with resultant biliary colic. If the gall bladder contracts against a spastic sphincter, distress may be produced as a result of sudden distention of the ducts. In most cases, however, irritability of the sphincter is probably on an organic basis.

Sphincter tone persists after cholecystectomy. The increased intraductal pressure which occurs in the absence of the gall bladder results in dilatation of the bile ducts.

A spastic sphincter of Oddi may be one of the causes of postcholecystectomy colic.

OPERATIVE AND NON-OPERATIVE METHODS IN THE MANAGEMENT OF COMMON DUCT LESIONS

R. RUSSELL BEST, M.D.
Associate Professor of Surgery
University of Nebraska
Omaha, Nebraska

In presenting this subject of common duct lesions, I am first going to discuss the diagnosis briefly. In the recent war, many of us saw many cases of jaundice. Occasionally, we were confronted with cases of suspected infectious hepatitis where severe distress and colic-like pain were described, and the differential diagnosis was difficult. Of the many cases I saw in consultation with several excellent internists, we erred in only one instance by advising an operation in a case of infectious hepatitis. This soldier had had repeated hospitalizations for jaundice and colic. I did not remove the gall bladder but merely excised a section of liver for microscopic study. I believe we, as surgeons, should be of some help to our medical colleagues by also being acquainted with the picture of infectious hepatitis. Pain, colic and jaundice, especially when attacks are repeated, favor a surgical jaundice. I know of no test which determines definitely and at all times whether the individual has a surgical jaundice or a nonsurgical jaundice, so we must depend largely upon the history and careful analysis of the many laboratory tests.

The jaundice of infectious hepatitis develops fairly rapidly but usually lasts only a week to ten days, after which the jaundice progressively subsides. Rarely is the stool acholic for more than a week. In cases with stones, whether colic is present or absent, the jaundice level is usually fluctuating but may or may not be prolonged. In jaundice due to malignancy, the icteric changes are continuous and progressive until surgical intervention. I believe we all delay surgical intervention when a patient is jaundiced. Usually one is not warranted to advise operation until after several weeks of observation unless the diagnosis of stone or malignancy can be definitely established.

Patients with jaundice are many times very uncomfortable during the time we are trying to make a diagnosis, attempting to improve liver function, correcting fluid balance and protein levels, and improving the prothrombin time. I have tried many means of relieving the intense itching. Usually 5 to 10 per cent glucose so-

lution intravenously gives relief for two to three hours or even longer. Ergotamine tartrate, in dosages of .25 mg. subcutaneously or 1 mg. orally, may be helpful, although this may be contraindicated where liver function tests show considerable damage. Many times it is not present in the jaundiced individual. In several cases, I have tried sodium thiosulfate in .5 gm. to 1 gm. doses intravenously, but certainly this is not the answer for all individuals. Novocaine intravenously over a 2-hour period has been advocated, using a 1 gm. dose in 500 c.c. of intravenous solution. Quite frequently this gives relief for some six to ten hours. The most helpful application for the patient to use himself is the following modified calamine lotion:

Phenol	dr. 1
Pulv. calamine prep.	dr. 1
Zinc oxide	dr. 2
Glycerin	dr. 2
Liquor hamamelis	oz. 1
Aqua Rosae	oz. 1
Milk of magnesia q.s. a.d.	oz. 6

Mix small amounts of this with equal amounts of Parapsyllium or Petrolagar and apply as necessary for itching.

This mixture without the oil gives only momentary relief in itching from jaundice, for as soon as the solution dries, itching is worse, as dry skin is more uncomfortable than moist skin. This accounts for mixing it with an oily base. I have been happy about the comfort this mixture affords patients.

When the decision has been reached that surgical interference is indicated and the patient has been properly prepared, regardless of whether or not the jaundice has subsided, the common duct must be opened and explored. If no obstructing agent is found along the common duct or hepatic duct, and the conclusion is reached that the diagnosis is in error, a section of liver should be excised for microscopic study. This will possibly confirm the existence of an intrahepatic and nonsurgical type of jaundice.

In cases of surgical jaundice, in addition to a history of jaundice, the common duct should be opened under the following conditions, namely, palpable stones or tumor within the duct, dilatation of the duct, sclerosis or thickening of the duct wall, history of repeated chills and fever, and small stones within the gall bladder. However, in the past seven years, I have not so frequently opened the common duct when small stones were present in the gall bladder because the biliary flush has proved quite successful in removing small stones and debris from the common duct. This confidence is also based upon the success of the flush in removing larger stones which have been visualized by choledochograms, and by a definite decrease in the postcholecystectomy syndrone in patients who have been operated upon for biliary tract disease and have had the biliary flush. In the last 100 cholecystectomy cases, the common duct was opened in twenty-four instances (24 per cent), and stones removed from the common duct in sixteen (16 per cent). At one time, I was opening the common duct in 40 per cent of the cases.

Is there danger in opening the common duct? I believe

TABLE I. INCIDENCE OF LIVER STONES IN CHOLELITHIASIS

very little harm results from this procedure. A stricture has never developed in my experience, and the only accident occurred very recently when I was working around the common duct in a heavy-set individual in whom I knew there was some anomaly but which I could not figure out. While we were opening the common duct, a severe hemorrhage occurred, filling the abdomen and operative field with blood. This was controlled immediately by pressure on the hepatic artery, as it looked like arterial blood. After clearing the field, oxidized gauze (Hemopak) was used and the bleeding was controlled. This is my only experience with a severe arterial hemorrhage controlled by oxidized gauze. Repeated exploration of the region did not disclose an end or side of a vessel which should be ligated. Fresh oxidized gauze was applied to the area, and no postoperative hemorrhage occurred.

The most frequent source of remaining common-duct stone is the stone which is overlooked at the first operation. Not infrequently the common duct is opened and explored and no stone found, but the delayed cholangiogram reveals the presence of such a stone. Probably the next most common source is the hepatic or hepatic-duct stone which reaches the common duct following operation. It is possible that stones may form in the common duct later, but it is most likely that the nucleus of such a stone is a small unidentified stone which later collects debris and precipitate. Also, small stones may be dislodged into the common duct during cholecystectomy.

What is the incidence of liver stones in cholelithiasis? Perusal of routine autopsy reports will not reveal such a finding. Rarely does the pathologist slice the entire liver sufficiently thinly and explore the intrahepatic ducts for stones. A few years ago, I thoroughly examined the liver at the autopsy table in thirty patients who had died of various causes but whose gall bladders contained stones. Two of these had stones within the ducts of the liver. The literature was then reviewed, but there were few reports on the true incidence of liver stones. Table I summarizes by findings in the literature. This is a collection of 456 cases of cholelithiasis where the liver was thoroughly investigated, and liver stones were found in thirty-five cases, an incidence of 7.5 per cent for liver stones in cases of cholelithiasis. This figure is certainly of some significance as to the etiology of the postcholecystectomy syndrome which has been caused by a common-duct stone.

It is my impression that if we produce a physiologic flush of the intrahepatic and extrahepatic ducts, unidentified stones in the common duct and debris remaning

in the common duct, which can be the nucleus of common-duct stones, may be flushed out and prevent later common-duct symptoms and difficulties. We are able to increase the bile flow by giving the patient a hydrocholeretic, which results in a 100 to 200 per cent increase of bile flow. The bile produced by a hydrocholeretic is thin and watery, differing from the average bile produced by a choleretic (plain bile salts). This increased flow of bile has been determined in a rather large group of patients and the resulting increased ductal pressure has also been measured in patients with an indwelling common-duct T-tube. Our experiments have been with decholin and procholon, but we have reason to believe that ketochol has the same effect. In establishing a flushing effect, one should take advantage of every means of relaxing the choledochal sphincter area, which would then permit passage of the stone, stones or debris into the duodenum. We feel that the following three-day regime has given the best results. Usually a rest of a few days to several weeks is given between flushes. Under no circumstances should the three-day biliary flush be given when the common duct is completely obstructed.

Three-day Biliary Flush Regime

1. Take three of the larger tablets (Procholon or Decholin) after each meal and at bedtime for three days.
2. Take 1 teaspoonful of magnesium sulphate in water each morning.
3. Take 2 tablespoonfuls of pure cream or olive oil before noon and evening meals and at bedtime.
4. On the first day, place one of the nitroglycerin tablets (1/100 gr.) under the tongue before each meal.
5. On the second day, dissolve one of the atropine tablets (1/100 gr.) in a little water and take before each meal.
6. On the third day, repeat the nitroglycerin tablets as on the first day.

There have been some rather dramatic expulsions of remaining stones from the common duct. That success has been attained in removing common-duct stones has been revealed by postoperative cholangiograms in about 40 per cent of the cases. Frequently, additional means have been employed to promote dislodgement of the stone. Daily irrigations with warm saline followed by warm olive oil are almost routine. Occasionally, warm iodized oil seems to be more beneficial. At times, additional antispasmodics are necessary to afford sufficient relaxation of the choledochal sphincter area. Aminophyllin in 7.5 grain doses has been used as recommended by Means and Delor, Gladstone, and Goodman and Cole. Arrest of the spasm of the sphincter area may be accomplished by instillation of 5 to 10 c.c. of a 1:500 solution of nupercaine solution, as recommended by Harris and Marcus of San Francisco. Fragmentation or chemical reduction of the stone has also proven most helpful in our experience. Pribam introduced ether as a solvent of certain gallstones, and later this was modified by Osterberg to a mixture of ⅔ ethyl ether and ⅓ ethyl alcohol, which we have used. There have been some reports that this drug has damaging effects on the liver. Boyce does not believe ether to be too dangerous. Raffl made some experimental studies of the effect of ether on cells of the liver and bile ducts and concluded that if provision is made for escape of the solution, so as to prevent the building up of too high an intrahepatic or intraductal pressure, cellular injury does not occur. He recommended a double catheter arrangement, the second tube being an escape vent for the vaporizing ether. We have depended upon careful manipulation of the plunger in the syringe, pulling it back as the patient's pain becomes severe and then reinjecting as the pressure decreases. A mixture of 3 c.c. of ethyl ether and 2 c.c. of ethyl alcohol has been used in our cases each day during the flush treatment. In every instance, the patient has complained of pain, but usually there is complete relief as the plunger of the syringe is drawn back. On one occasion, where we had used this solution some six times with six series of flushes, the patient became rather listless for a few days, and we suspected some possible liver shock. The amount of bile flow decreased and became rather light in color. We immediately instituted all means of building up liver function, and the bile flow returned to normal in four days. A check-up cholangiogram revealed that the stone in the common duct had been dislodged. A few days later, the T-tube was removed, and the patient has remained well, it now being over a year. In this particular instance, three flush treatments—two with daily instillations of the ether-alcohol mixture—had been tried without success. The patient was sent home for three months and advised to take the three-day flush treatment every two weeks. On her return to the hospital, and following three more flush treatments with ether-alcohol instillations, this questionable effect on liver function occurred. In other cases, we have been successful in dislodging stones after repeated efforts, which included the patient going home for several months and then returning for further treatment. Walters and Wesson, Morton and a few others have reported success with the use of the ether-alcohol mixture.

There has been a search for a more effective solvent which is innocuous to living tissue. Narat and Cipolla in 1945 reported on the use of chloroform. Chloroform, like ether, is a solvent for cholesterol, but in addition causes dissolution of bile pigment. They injected warm chloroform (heated to 38° C. or 100.4° F.) into the gall bladder and common duct of dogs, and then after sacrificing the animals, studied the microscopic sections of the biliary ducts and liver. They concluded that injection of chloroform did not produce any demonstrable changes in the liver, gall bladder or extrahepatic ducts. However, they felt that repeated injections in the postoperative period should be discouraged, as they might represent a potential hazard. They favor the use of chloroform at the operating table in the management of the elusive stone. We have used chloroform on two patients, and in one case (two instillations), in conjunction with the biliary flush, the stone was dislodged. We used 5 c.c. of heated chloroform on two successive days. However, until after further observation, one should be a little cautious in using chloroform.

Goldman, Jackman and Eastman reported on the use of Solution G as a solvent for remaining common-duct stones and detailed the success in two cases. This is an interesting report, as the *in vitro* experiments were disappointing. However, the method should be kept in mind

and tried further. We have used it in one patient without success, but also all other methods failed. The formula of Solution G is as follows:

Citric acide (monohydrated)	32.25
Magnesium oxide (anhydrous)	3.84
Sodium carbonate (anhydrous)	4.37
Water q.s. a.d.	1000.00 c.c.

This solution is permitted to drip into the common-duct T-tube at the rate of 30 drops per minute, and may be repeated several times daily.

It is our routine in all cases of biliary tract operations to start the biliary flush on about the eighth postoperative day and repeat it in about two weeks. In cases where the delayed cholangiogram reveals a stone in the lower end of the common duct, the biliary flush is used in conjunction with the other agents as just discussed. In these cases, we have been successful in removing stones in about 40 per cent of the cases. Some of these cases have been primarily operated upon by me and others by surgeons elsewhere.

Secondary operations on the biliary tract are difficult and carry a greater hazard than the primary operation. Therefore, this non-operative management is strongly recommended before a secondary operation is considered. Even the secondary operation may be unsuccessful in locating and removing the elusive stone. We have seen as many as eleven stones remaining in one common duct, and by the flush method have recovered the stones from the stool. Also we have dislodged some large intact stones from the common duct and recovered these from the stool when our imagination could barely stretch to the possibility that these stones had escaped through such a narrow area. Improvements in methods for fragmentation and dissolution of the common-duct stone are wanting.

The development of a stricture of the common duct following cholecystectomy is a major complication. This may express itself by development of a biliary fistula with acholic stools or appearance of jaundice. I have not been successful in my attempts with plastic procedures, and either depend on anastomosing the proximal duct to a loop of jejunum or placing some type of rubber or vitallium tubing in the duct and reconstructing the duct over this material. Where the hepatic duct is anastomosed to the intestine, I prefer to divide the upper jejunum and anastomose the distal end to the hepatic duct over a vitallium tube (Cole) and re-establish continuity by an end-to-side anastomosis. Where continuity of the duct can be re-established, which is probably the method of choice because of preserving the common duct sphincter mechanism, I prefer using the vitallium tube. I have modified the ends of my vitallium tubes slightly by having the manufacturer drill six staggered holes near the upper end. Usually the upper end of this metal tube projects into the portohepatis area of the liver, and I have felt that some of the poor results reported have probably been occasioned by the tube draining one segment of the liver but blocking drainage from the other duct or ducts converging in this area. These small perforations may prevent this complication. The flange of the vitallium tube is, if at all possible, fixed into the liver or scar tissue with a silk suture. All of these patients and all other patients with biliary-intestinal anastomoses are directed to take the bile flush the first three days of each month or oftener. Naturally if the choledochal sphincter mechanism is not functioning, it is not necessary to use the antispasmodic agents. Many of these patients are also advised to take small daily doses of one of the hydrocholeretics (two tablets night and morning). The free flow of this watery bile tends to prevent the formation of a precipitate in the tube and if corrosion and encrustation do develop, the thinner bile makes an easier exit.

Malignancy obstructing the lower end of the common duct, whether primary in the duct, papilla of Vater, duodenum or pancreas, usually requires a similar procedure, entailing transection across the lower end of the common duct and removal of the duodenum and head of the pancreas, thus destroying the ductal system between the pancreas and intestinal tract. The one-stage operation is preferable, but occasionally the two-stage procedure is advisable. If the two-stage procedure seems indicated, the first stage consists of transecting the jejunum quite some distance from the duodeno-jejunal angle and anastomosing the distal end to the gall bladder or common duct. An anterior gastrojejunostomy is made and the proximal end of jejunum anastomosed end-to-side to the single limb of the jejunum leading to the hepatic area. If the second stage does not seem advisable, short-circuiting routes for the obstructed bile and the duodenal contents have been established. If the lesion is inflammatory, adequate rest has been provided for the duodenum and the lower end of the common duct. In the one-stage procedure, Cole's modification of the Whipple method is preferred. At the present time, I feel that the open end of the transected pancreas should be implanted into the side of a limb of the jejunum. My own experiences with this procedure have not been very favorable as to longevity before recurrence. As one reviews case reports, three- and five-year cures are unusual. In fact, in some cases where only the palliative procedures as described in the first operation for the two-stage procedure have been used, comfort and longevity have been about the same as with the radical procedure. Error in diagnosis between malignancy and an inflammatory lesion involving the pancreas is sometimes a problem in surgery of this region.

Discussion

DR. JAMES HAYES: I would like to ask Dr. Best if he uses his flush procedure on all T-tube cases whether they have any unfavorable symptoms or not.

DR. BEST: Yes, in all cases. In routine cholecystectomy cases, the patient is given the flush on about the eighth postoperative day, and this is repeated two weeks later. After removal of a T-tube, I usually wait twenty-four to forty-eight hours and then start the biliary flush. This is repeated two weeks later.

DR. HAYES: How long is it since you put in your first vitallium tube? I put one in about six years ago. The patient has been perfectly well since. Two years after operation the tube could be seen in place. Today the tube does not show with the x-ray, but the patient seems perfectly well. I have two other patients with vitallium tubes in for four and five years, respectively. They have both been perfectly well since the operation. All of these patients had been operated upon more than once before the vitallium tubes were inserted. I was wondering how long you had observed this tube in place?

DR. BEST: Two years is the longest I have had a vitallium tube in place. I believe that putting the holes in the end of the tube is an advantage. I can tell better in another year or two.

DR. CLARENCE DENNIS: I helped Dr. John Paine put a tube in before he joined the army, and while he was away I had to take that tube out. It had passed halfway into the duodenum and had become lodged and covered with concretions. I didn't start the patient with a biliary flush, but I would have been better off if I had. I had to go back and take the vitallium tube out. A silk suture had been put through the flange to hold the tube in place.

I would like to ask another question. With the anastomosis of the type Dr. Allen described, have you found that biliary flushes are successful in taking care of the symptoms of chills and fever when they have developed? I ask this in view of the fact that the biliary flush is designed to depend on the effect of the sphincter in the lower end of the common duct. Good results have followed use of the flush at the University.

DR. BEST: The biliary flush consists of two elements, namely, production of a thin watery bile and measures to relax the sphincter mechanism. In choledocho-intestinal anastomosis, the production of thin bile and its flushing effect on the tubal system are the only factors to consider.

DR. O. J. CAMPBELL: I would like to ask Dr. Best whether I was misled by my experiment in attempting to dissolve some gallstones which I had previously removed from a gall bladder. The circumstances were as follows:

Following removal of a gall bladder full of stones, then removal of the stones from the common duct, the patient subsequently showed symptoms of a remaining common-duct stone. The T-tube was still in place, and the question arose as to whether to reoperate or to attempt to flush the stones. I took some of the stones which were fresh from the gall bladder, put them in olive oil and alcohol. I do not believe that I used chloroform. At the end of seventy-two hours they were still as solid as they were originally. On this basis I decided that flushing was not feasible, and so I surgically removed the remaining stones from the common duct.

Under these circumstances, should I have tried to flush anyway?

DR. BEST: Most certainly I would have tried the flush regime, and if not successful the first time, I would have repeated it.

RETINITIS PIGMENTOSA

(Continued from Page 157)

Case Reports of a Sister and Brother

Case 1—J. B., a girl, aged ten, had suffered from nystagmus since fifteen months of age. Her eyes had turned in since she was a baby. She had always been unable to see at night, and had a great deal of difficulty with her school work. There was no history of eye trouble either in the father's or mother's family. The father and mother were not related.

Examination: Vision of the right eye was 4/200; vision of the left eye was 3/200.

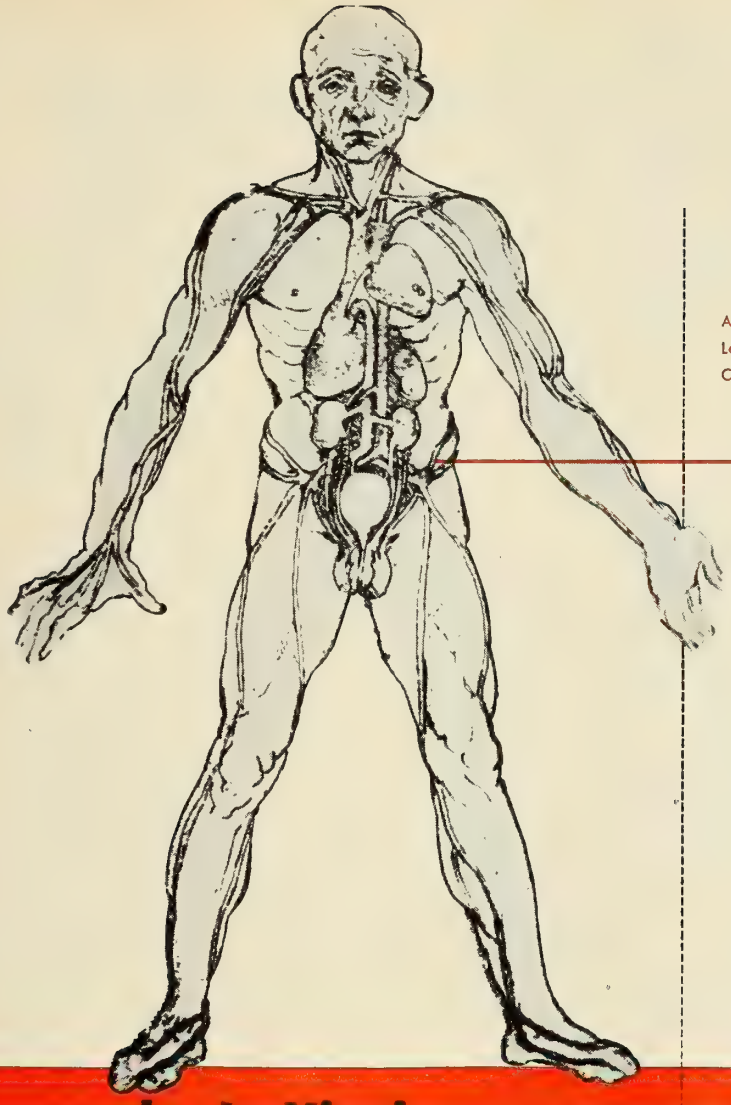
Manifest refraction:

R.E. $+ 8.00S = + 1.000 \times 90 = 5/200$
L.E. $+ 8.00S = + 1.250 \times 90 = 5/200$

Fundus examination revealed extensive pigmentary changes over the entire fundus except in the macula area of both eyes. Visual fields were contracted to one-half the normal size. Color vision was normal.

Case 2.—D. B., aged six, a brother of J. B., had suffered from nystagmus since four months of age. His eyes turned in. He had worn glasses since he was two years old. Vision in the right eye was 2/200, in the left eye, 1/100.

Manifest refraction:



R.E. $+ 5.50S = 20/200$
L.E. $+ 5.50S = 20/200$

Pigmentary changes were seen in the periphery of both fundi, about half as numerous and smaller in size than the pigmentary changes in the fundi of his sister. In the peripheral retina there were several areas consistent with gyrat atrophy of the choroid.

These patients now are enrolled in a sight-saving class. Soon they will study braille, as their vision will surely fail.

FOOD SUPPLY

The people of the world are suffering today from a shortage of fats and oils. More than half a century ago, Dr. John Harvey Kellogg made an excellent suggestion, which if carried out would have added greatly to our food resources. It was to plant nut trees on both sides of every highway in the United States. If this had been done, the trees today would be bearing enough fruit to supply huge quantities of protein of the finest quality, as well as excellent oils. While much valuable time has been lost, it is not too late to start such a tree-planting program now. This plan fits into the reforestation project on which we have embarked.—*Good Health,* November, 1947.

INTERNATIONAL SURGICAL ASSEMBLY

The Sixth International Assembly of the International College of Surgeons will be held in Rome, Italy, at the invitation of the Italian Government, during the week of May 16-23, 1948, under the presidency of Professors Raffaele Bastianelli and Raffaele Paolucci of Rome, and Mario Dogliotti of Turin. The Secretary of the Assembly is Prof. Giuseppe Bendandi of Rome. Attendance is not limited to the membership of the College. All surgeons in good standing in their medical organizations are invited.

Scientific meetings, scientific and commercial exhibits, visits to the Universities of Turin and Milan have been arranged, together with tours to other medical centers in Europe. A special exhibit of ancient texts on surgery is being arranged by Prof. Davide Giordano of Venice, Honorary President, under the active presidency of Prof. Adalberto Pazzini, Professor of History at the University of Rome. This extraordinary exhibit dealing with ancient surgery will be on display in the Vallicelliana Library in one of the historical buildings of the Vatican.

Detailed information may be obtained from Dr. Max Thorek, General Secretary, 850 Irving Park Road, Chicago 13. For travel information, address the All Nations Travel Bureau, 38 S. Dearborn Street, Chicago, the official travel representatives for this Assembly. Those desiring to present scientific papers should address Dr. Karl Meyer, Cook County Hospital, Chicago; Dr. Henry W. Meyerding, Mayo Foundation, Rochester, Minnesota; or Dr. Herbert Acuff, Acuff Clinic, 514 W. Church Street, Knoxville, Tennessee. Those from Canada should direct their inquiries to Dr. Lyon Appleby, 925 W. George Street, Vancouver, B. C.

FELLOWSHIPS IN PHYSICAL MEDICINE

In the past year the American Board of Physical Medicine has been established as a recognized medical specialty. Qualifications for examination for the Board include three years of clinic, hospital and laboratory training in institutions approved by the Board. The Department of Physical Medicine of the University of Minnesota Medical School has established fellowships of one to three years' duration providing the experience and training necessary to fulfill these qualifications.

The departments and institutions affiliated with the Department of Physical Medicine for providing this training include the basic science departments of the Medical School, the Peripheral Vascular Clinic, the Department of Neurology, Minneapolis General Hospital, Rosemount Poliomyelitis Hospital, Minneapolis Veterans Hospital, and the Section on Physical Medicine of the Mayo Clinic. Rotating fellowships have been set up through these departments to provide experience in diagnosis and treatment of orthopedic, neurologic, vascular, and arthritic diseases. Within this broad general program it is possible to concentrate work on any field of special interest. Likewise, for physicians interested in fields closely related to physical medicine such as orthopedics and neurology, it is possible to arrange special programs concentrating on the problems of those fields. In addition, time and facilities are available to do research on fundamental or clinical problems related to the practice of physical medicine.

The stipend of the Medical School fellowship is $1,380 per annum. Veterans may obtain subsistence pay up to $2,400. The fellowships at the Minneapolis Veterans Hospital carry a stipend of $3,600. All fellowships are granted annually and are renewable for three years.

FELLOWSHIP IN HEALTH EDUCATION

Fellowships leading to a Master's Degree in Public Health in the field of Health Education are again being offered to any qualified United States citizen between the ages of twenty-two and forty, according to a statement released in January by the United States Public Health Service, Federal Security Agency. Funds are available through a grant from the National Foundation for Infantile Paralysis.

Candidates must hold a Bachelor's degree from a recognized college or university at the time the application is filed, and must be able to meet the entrance requirements of the accredited school of public health of their choice. Proof of acceptance at such a school must be furnished before applications are submitted to the Fellowship Awards Committee for consideration. In addition to the Bachelor's degree, courses in the biological sciences, sociology and education are required. Training in public speaking, journalism, psychology and work in public health or a related field is considered desirable.

The fellowship consists of eight or nine months of academic work, which begins with the fall term in 1948, and three months of supervised field experience in community health education activities in a local health department. The academic training includes courses in

In behalf of the medical profession

. . . the message reproduced below will appear in LIFE and other national magazines, reaching more than 23 million people.

A reproduction in full color will be sent on request. Write Parke, Davis & Company, Detroit 32, Michigan.

Some things you should know about the common cold

No. 209 in a series of messages from Parke, Davis & Co. on the importance of prompt and proper medical care.

MOST PEOPLE in the United States and Canada have two or more colds a year, each lasting about two weeks and causing a considerable amount of stuffy discomfort.

The danger of the common cold lies mainly in the other infections that may follow after it. For a cold lessens your resistance, and is likely to pave the way for other, more serious, respiratory ailments.

Sinusitus, ear infections, bronchitis, and the various forms of pneumonia are frequently ushered in by a cold. Pneumonia, particularly, is likely to attack a person who is overtired, or run-down because of a severe cold.

True, many of these respiratory diseases are not as dangerous as they used to be. (Modern infection-fighting drugs—such as penicillin and the sulpha drugs—offer highly effective treatment for many cases.)

But, of course, it is always better to *prevent* a serious illness whenever possible.

If you have a cold, it's just good sense to stay away from people, to avoid spreading the infection; and to get plenty of rest—in bed if possible.

If your cold is accompanied by fever, a persistent cough, or a pain in the chest, face, or ear, call your doctor at once.

The sooner you seek his help, the more he can do to help you avoid a long and serious illness.

And, in the case of children, an early examination may disclose that what appears to be only a cold may instead be a starting symptom of an entirely different disease, such as measles or scarlet fever.

SEE YOUR DOCTOR. Never try the foolhardy experiment of dosing yourself. Your doctor's treatment of one illness may be quite different from his treatment of another illness which appears the same to you.

Let your doctor diagnose your ailments. Let him decide what treatment is best for your particular case. Then follow his instructions to the letter. His advice is the only advice you should take on any question that concerns your health.

FELLOWSHIP IN HEALTH EDUCATION

(Continued from Page 198)

public health administration, epidemiology, public health and school education, problems in health education, community organization, information techniques, and others.

Veterans are encouraged to apply, and will be paid the difference between their subsistence allowance under the GI Bill of Rights and the monthly stipend of $100 for single veterans or $150 for married veterans. Employes of State or local health departments are not eligible, since Federal grants-in-aid are provided through the States for such training.

Information and application blanks may be obtained by writing the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, New York.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club, Saint Paul, on the evening of January 13.

Elected to active membership were Dr. Roger W. Howell, Dr. Charles M. Jessico and Dr. Lawrence E. Schneider.

The program for the evening included two inaugural theses, one by Dr. Burton P. Grimes and one by Dr. Leonard A. Titrud. The title of Dr. Grimes' paper was "Murder Under Twenty-one," while Dr. Titrud's paper was entitled "Effect of High Altitude on Brain Injury Cases."

PHI DELTA EPSILON LECTURESHIP

The Minnesota Graduate Club and Alpha Xi Undergraduate Chapter of the Phi Delta Epsilon Fraternity announce their gift of an annual lectureship to the Medical School of the University of Minnesota. The first lecture will be given February 26, 1948, in the Medical Sciences Amphitheater at the University of Minnesota, by Dr. William Roemmich of the United States Public Health Service, whose topic will be "The Chest X-Ray Survey of Hennepin County." The meeting will be preceded by a banquet when the lectureship will be formally presented to the University and accepted by Dean Harold S. Diehl of the Medical School.

SIGMA XI LECTURE SERIES

"The Challenge of Cancer" was the theme of the three 1948 Sigma Xi lectures given at the University of Minnesota during February. Sponsored jointly by the Minnesota chapter of Sigma Xi, scientific research society, and the Minnesota Division of the American Cancer Society, the lectures were presented in Northrop Memorial Auditorium on the University campus and were open to the public.

The first lecture was given on February 6 by Dr. John J. Bittner, director of the Division of Cancer

facts about Formulac

What is FORMULAC Infant Food? It is a concentrated milk containing *all the vitamins and minerals* a normal, growing baby is known to need. Incorporating the vitamins *into the milk itself* lessens the risk of error in supplementary administration.

FORMULAC contains vitamins of the B complex, Vitamin C in stabilized form, Vitamin D (800 U.S.P. units), copper, manganese, and easily assimilated ferric lactate. No carbohydrate has been added.

FORMULAC is in convenient liquid form, for easy preparation. The addition of carbohydrate—in the type and amount the individual child needs—creates a complete infant diet. FORMULAC is used successfully both in normal and in difficult feeding cases.

FORMULAC has been clinically tested and proved. It is promoted ethically. A product of National Dairy Research, it is available at grocery and drug stores everywhere, priced within range of even low budgets.

• For further information about FORMULAC, drop a card to National Dairy Products Company, Inc., 230 Park Avenue, New York 17, N. Y.

Biology in the University of Minnesota Medical School, and was on the subject, "Investigating the Causes of Cancer."

Second lecturer in the series was Dr. Claude F. Dixon, professor of surgery in the Mayo Foundation, Rochester, who, on February 13, spoke on "Cancer Treatment Today."

Concluding the series, Dr. Owen H. Wangensteen, chief of the Department of Surgery in the University Medical School, spoke on February 20 on the subject, "The Cancer Problem Today."

RED RIVER VALLEY SOCIETY

Election of officers for 1948 highlighted the annual meeting of the Red River Valley Medical Society, held in Crookston on December 16. Named as president of the organization was Dr. M. J. Bechtel, Warren, while Dr. George Sather, Fosston, was elected vice president, and Dr. R. O. Sather, Crookston, was re-elected secretary-treasurer.

Elected as delegates to the state association were Dr. T. F. Bratrud, Thief River Falls, and Dr. Eskil Erickson, Halstad, with Dr. C. H. Holmstrom, Warren, and Dr. John Cameron, Crookston, elected as alternate delegates. Dr. K. W. Kovey, Mahnomen, was elected censor for a three-year term.

Principal speaker of the evening was Dr. J. F. Norman, Crookston, who discussed prepaid medical care.

WINONA COUNTY SOCIETY

Dr. Lewis I. Younger, Winona, has been elected president of the Winona County Medical Society to succeed Dr. S. J. Hamlon, St. Charles. Also elected to office at a recent meeting of the group was Dr. F. J. Vollmer, Winona, vice president, while Dr. Paul Heise and Dr. L. F. Johnston, both of Winona, were re-elected secretary and treasurer, respectively.

Re-elected as delegate to the state association was Dr. R. H. Wilson, Winona. Announcement was made that the Southern Minnesota Medical Association would hold its annual convention in Winona during August.

FREEBORN COUNTY SOCIETY

At the annual meeting of the Freeborn County Medical Society, held on December 17 at Hotel Albert in Albert Lea, Dr. Leo R. Prins was elected president of the organization. He succeeds the late Dr. Paul Gamble of Albert Lea.

Other officers elected at the meeting were Dr. J. P. Person, vice president; Dr. E. S. Palmerton, secretary, and Dr. R. A. Demo, treasurer, all of Albert Lea.

CONTAMINATION TEST of penicillin broth—*one of the 138 separate tests carried out by Abbott in the production of dependable penicillin.* Tubes of sterile nutrient are inoculated with samples of broth from the fermentation tanks and then incubated. Broth contaminated by bacteria turns cloudy; noncontaminated broth remains clear. Besides bacteria, other invaders to guard against are yeasts and wild molds. Some contaminants merely use up nutrients and reduce penicillin yield; others—such as the gram negative bacteria of the coliform group—produce penicillinase, which destroys the penicillin in the broth.

Penicillin mold, new growth.

Clear, sterile broth.

"all clear" for better penicillin

Tests and more tests—138 in all—make Penicillin Abbott a product you can use *with confidence.* These 138 separate Abbott tests—exclusive of those made by the Food and Drug Administration—guard the product through tanks, filters, dryers, filling machines and other stages. Besides checking on contamination, the 138 tests cover potency, sterility, pyrogens, toxicity, G content, heat stability, pH, moisture, weight, solubility and crystallinity. They are your assurance that Penicillin Abbott—whether in cartridges, vials, tablets, troches or ointments—is absolutely dependable. Your pharmacist has Abbott Penicillin Products in stock and will be pleased to fill your needs. For descriptive literature, just send a card to ABBOTT LABORATORIES, North Chicago, Illinois.

WOMAN'S AUXILIARY

Blue Earth County

The Blue Earth County Auxiliary was hostess at a dinner meeting held at the Century Club, Mankato, on November 19, to the Nicollet-Le Sueur and Redwood-Brown Auxiliaries. Dr. Leonard Lange, obstetrician and gynecologist on the teaching staff of the University of Minnesota gave a talk to the doctors and their wives. About 100 attended. Mrs. A. A. Schmitz and Mrs. John Michelson were in charge of the social program. Mrs. W. W. Franchere is president of the Blue Earth Auxiliary.

Renville County

Renville County Auxiliary members were entertained at a Christmas party at the home of Dr. and Mrs. O. H. Johnson of Redwood Falls on December 9. Mrs. S. F. Ceplecha and Mrs. W. A. Brand assisted.

The Christmas seal essays were read and judged. Ruth Peterson of Sacred Heart received first prize of $5.00; Larry Notman of Franklin, second prize of $3.00, and Joan Benesh of Bird Island, third prize of $2.00 Several more subscriptions to *Hygeia* were received.

Following an exchange of gifts, the physicians, together with their speaker of the evening, Dr. George Agaard of Minneapolis, joined the Auxiliary members at the Johnson home and partook of a lunch of Christmas delicacies brought by several of the Auxiliary members.

On January 13, members of the Woman's Auxiliary to the Renville County Medical Society met for a 6:45 dinner at the Sweet Shop in Olivia. While the Doctors enjoyed a talk by a former member, Dr. W. Bushard of Edina, the Auxiliary members had a short business meeting. The rest of the evening was spent in preparing two scrapbooks. Members had brought cloth for pages and pictures. These scrapbooks were given to a hospital. All dues for the new year are in!

St. Louis County

The Woman's Auxiliary to the St. Louis County Medical Society held a meeting on January 13 at which Dr. F. S. Elias of Duluth, who is Council Chairman of the Minnesota State Medical Association, gave a talk on "Health Legislation."

The organization has a membership this year of 150 which includes forty members of the Range branch. They have planned a busy year. They are contributing to the Association for the Physically handicapped, Red Cross, Christmas Seals, Cancer Control, Society for the Prevention of Blindness. They help sponsor the Tuberculosis Essay Contest, camps for the Y.W.C.A. and Girl Scouts. They are also continuing their scholarship fund for nurses. To help them carry on this philanthropic and public health work, the members held a one-day rummage sale which netted over $300.

Washington County

The Woman's Auxiliary to the Washington County Medical Society met at the home of Mrs. Demeter Kalinoff on December 9. This was a Christmas Party so a program was given and members exchanged gifts. They decided to send a gift to their shut-in member.

The Auxiliary met at the home of Mrs. Russell E. Carlson on Tuesday, January 13, for a dessert luncheon. Miss Maurine Erickson, County Social Worker, gave an interesting talk on her work.

Early in January, Dr. William O. McLane, who was affiliated with the Wadena Clinic for several months, announced that he was no longer associated with the clinic and was planning to build new offices for his practice in Wadena. Until his new offices were completed, he planned to conduct his practice from his home at 219 Second Street N. W. Dr. McLane specializes in diseases of the eye, ear, nose and throat.

* * *

Streptomycin was the subject of two talks given in the East during January by Dr. H. C. Hinshaw, Rochester. On January 8 he spoke at a meeting of the New York Academy of Medicine, in New York, on the topic, "Clinical Evaluation of Streptomycin Therapy in Tuberculosis and Other Infections." On the following day, speaking in Philadelphia at a meeting of the Eastern Section of the Trudeau Society, he discussed "Clinical Problems of Streptomycin Therapy."

* * *

Acting president of the Minnesota Division, American Cancer Society, Dr. Arthur H. Wells, Duluth, was recently elected a regional director on the national American Cancer Society board of directors. Representing Minnesota, Wisconsin, Michigan, Illinois, Indiana and Iowa on the national board, Dr. Wells succeeds the late Dr. William A. O'Brien, who was president of the state unit and regional ACS director at the time of his death.

* * *

Two out-of-state talks were given by Dr. Gordon R. Kamman, Saint Paul, during the month of January. In Milwaukee, Wisconsin, on January 9, Dr. Kamman spoke before the Milwaukee County Medical Society on "The Psychobiologic Basis for the Psychosomatic Concept." In Minot, North Dakota, on January 21, his subject was "Neurotic Problems Confronting the General Practitioner" when he spoke at a meeting of the Northwest District Medical Society.

* * *

A campaign was launched in Albert Lea in December to raise funds to establish a well-equipped children's ward in Naeve Hospital in memory of three brothers who lived, practiced medicine, and died in Albert Lea.

Backing the memorial campaign were friends and admirers of the late Doctors Will, Ross and Paul Gamble. Eldest of the three brothers, Dr. Will Gamble, began his practice in Albert Lea early in the

1920's and was joined there soon afterwards by his brothers. Dr. Ross Gamble died several years ago; both Dr. Paul Gamble and Dr. Will Gamble died during the summer of 1947.

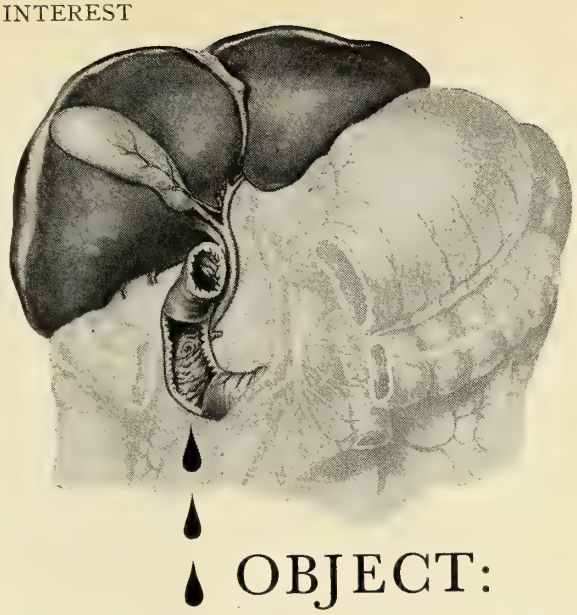
* * *

Offices for the practice of internal medicine have been opened by Dr. Eugene Rinkey at 749 Lowry Medical Arts Building, Saint Paul. A graduate of the University of Minnesota Medical School in 1940, Dr. Rinkey interned at St. Mary's Hospital, Minneapolis. After practicing at Redwood Falls for a year, he served in the army from 1942 until 1945 when he was discharged as a captain. During the past year Dr. Rinkey was a resident at Ancker Hospital, Saint Paul.

* * *

Three formerly separate sections of the army medical department were recently combined into a single unit under the command of a former Mankato woman. Chief of the new women's medical specialist corps, which now includes the dietitian section, the physical therapist section, and the occupational therapist section of the army medical department, is Colonel Emma E. Vogel, a former resident of Mankato, regarded by the surgeon general's office as the nation's outstanding physical therapist.

* * *



Under the direction of Dr. Walter A. Fansler, clinical assistant professor of surgery at the University of Minnesota, a continuation course in proctology as held in Minneapolis during the week of February 2 to 7. The course consisted of lectures at the University's Center for Continuation Study and clinics at Minneapolis General Hospital and Fort Snelling Veterans Hospital. Guest lecturer for the one-week course was Dr. Harry E. Bacon, head of the Department of Proctology at Temple University Medical School.

* * *

The Mississippi Valley Medical Editors Association is considering changing its name at its meeting next fall to the Mississippi Valley Medical Writers Association. It is pointed out that whereas all medical editors are writers, all medical writers are not editors, and since one of the principal purposes of the association is the improvement of medical writing, the change seems desirable. That the change in name will be made seems a foregone conclusion. Interested medical writers should contact Dr. Harold Swanberg, Secretary, 209 W. C. U. Building, Quincy, Illinois.

* * *

Dr. Lawrence W. Rember has been appointed executive assistant to Dr. George F. Lull, secretary and general manager of the AMA. Dr. Rember will be in charge of public relations, a task for which he is well qualified, having been director of public relations for the Blue Cross Plan Commission of the American Hospital Association and public relations director of the seventeen-state midwestern area of the American National Red Cross. He received an M.A. degree in journalism from Northwestern University after obtaining his B.A. degree at the University of Wisconsin, where he majored in journalism and commerce.

OBJECT: DRAINAGE

In discussing the management of chronic cholecystitis without stones, Albrecht states:

"The object of the medical procedure is to assist in draining an infected organ."*

The specific hydrocholeretic action of Decholin (chemically pure dehydrocholic acid) accomplishes this purpose.

Decholin induces bile secretion which is thin and copious, flushing the passages from the liver to the sphincter of Oddi, and carrying away infectious and other accumulated material.

How Supplied: Decholin in 3¾ gr. tablets. Packages of 25, 100, 500 and 1000.

*Albrecht, F. K.: Modern Management in Clinical Medicine, Baltimore, The Williams and Wilkins Co., 1946, p. 170.

ELKHART, INDIANA

Staff members of St. Luke's Hospital, Duluth, at their November meeting heard Dr. Richard Varco, of the Department of Surgery of the University of Minnesota, speak on "The Surgical Treatment of Certain Congenital Defects of the Heart and Great Vessels."

At the December meeting of the staff, papers were presented by Dr. S. H. Boyer, Jr., Dr. E. I. Parson, and Dr. J. J. Coll, all of Duluth. The January staff meeting had as the principal speaker, Mr. James Hamilton, of the Department of Hospital Administration, University of Minnesota.

Two new appointments were made in January by the Minneapolis City Health Department. Miss Helen Hestad, former assistant director of Minneapolis Community Health Service, was appointed Maternal and Child Health Nursing Consultant in the Bureau of Public Health Nursing. Mrs. Grace Henshaw Babcock, formerly with the American Red Cross and voluntary public health nursing agencies in Minneapolis, was appointed Mental Hygiene Consultant, a newly created position in the Bureau of Public Health Nursing. The two appointments were made possible by maternal and child health funds from the Minnesota Department of Health.

Dr. Edgar V. Allen, who has been with the Mayo Clinic since 1930 and chief of a section in internal medicine since 1936, has been appointed chief of the Division of Internal Medicine at the Cleveland Clinic, a nonprofit institution, second largest of its type in the United States. Dr. Allen was graduated from the University of Nebraska in 1925; he obtained an M.S. degree from the University of Minnesota in 1932. During 1929 and 1930 he studied in Germany and England on a fellowship from the National Research Council. In World War II he served as a colonel in the medical corps of the army and was consultant in medicine for the Seventh Service Command.

* * *

After more than fifty years of practice in Fergus Falls, Dr. W. W. Drought is closing his office. Dr. Drought began his medical practice in Fergus Falls in partnership with Dr. A. B. Cole, one time state senator from Otter Tail County. Later, Doctors Cole and Drought were affiliated with a Dr. Kittelson, with offices in the First National Bank Building in Fergus Falls. Dr. Kittelson later withdrew from the group to open an individual practice. After the death of Dr. Cole, many years ago, Dr. Drought maintained the practice by himself.

The Lyon-Lincoln County Medical Society recently completed its thirty-sixth semi-annual postgraduate extension course. Initiated following World War I, each course has consisted of four to six meetings held on consecutive Tuesday evenings, with addresses by outside or local physicians. During World War II, recourse was had to medical motion pictures, which have proven valuable in the educational field. With a society membership of only twenty-one, the attendance at the

dinner meetings has been as high as fifty-four. The society is to be congratulated on its accomplishment, which, as far as is known, is unique in the territory outside the large cities of the state.

* * *

Popular response to a talk given before the Winona Kiwanis Club in August, 1947, brought Dr. Benjamin Spock, Rochester, back to Winona on February 3 as principal speaker at the Council Founders' Day program of the Winona City Parent-Teacher Association. After hearing Dr. Spock at the Kiwanis Club meeting speak on "How Grandpa Should Talk to His Grandchildren," residents of Winona urged that the Mayo Clinic child health authority be brought back to the city for another talk. Dr. Spock complied, and at the PTA meeting in February he presented the subject, "The School-Age Child."

* * *

Christmas was merrier for children in Red Wing this last season because of Dr. L. E. Claydon's ingenuity in constructing outdoor decorations.

On the porch of his home, in a setting of lighted fir trees and holly, the Red Wing physician installed a life-size figure of Santa Claus seated before a model pipe organ. Records of organ music could be "piped" from the house to the porch, and a concealed cord led from Santa into the house. As children would pass by in the evening, Dr. Claydon would turn on the music and start manipulating the cord—and Santa would nod and sway over the keyboard, playing joyous Christmas carols. The children loved it, many of them climbing onto the porch to give Santa a hug and a kiss—a satisfying reward to Dr. Claydon, who brought Santa to life in Red Wing.

The annual gold medal award for the outstanding "family doctor" was presented this year to Dr. Archer C. Sudan, a Colorado physician, by the AMA House of Delegates while assembled in Cleveland in January.

The names of several hundred general practitioners had been submitted to the AMA by medical and non-medical groups. Three names were voted upon by the House of Delegates—Dr. A. C. Sudan, Kremmling, Colorado; Dr. W. L. Presley, Due West, South Carolina, and Dr. Jacob T. Oliphant, Farmersburg, Indiana.

Dr. Sudan, a native of Sioux Falls, South Dakota, left the University of Chicago Medical School in 1926, where he was a teacher and research worker, to locate in a mountain district of Colorado where he had recognized the urgent need for a physician while on a fishing trip. He has just completed a term as president of the Colorado State Medical Association.

MAY-O-LITE Reduces Reflection Increases Light Transmission

For many, far too many, years wearers of glasses have been handicapped and irritated by surface reflections. Reflections produce confusing, annoying "ghost images" on the lens surface. Reflections also cause eye and mental strain.

You can now minimize this handicap to the point of near-elimination.

You can do it by including May-O-Lite's Low Reflection Lens Coating in your lens prescriptions.

This revolutionary May-O-Lite process reduces surface reflection 75 to 90%—yet increases transmission of light. It increases the life of the lens surface, too—because Low Reflecting Lens Coating hardens the lens surface and helps to reduce surface scratches.

Developed for the armed services during the war to improve image definition in military instruments—our Low Reflection Lens Coating is now available to your patients. It is obtainable through most manufacturing and dispensing opticians. Write for a descriptive pamphlet and a treated sample of glass today.

On January 1 it was announced in Ortonville that Dr. Clarence S. Youngstrom, of La Crosse, Wisconsin, was joining the staff of the Ortonville Clinic where he would be associated in practice with Dr. D. M. O'Donnell and Dr. J. F. Karn.

A graduate of the University of Nebraska in 1938, Dr. Youngstrom interned at the U. S. Marine Hospital in Seattle, Washington, later completed residencies at the University of Wisconsin General Hospital, at Milwaukee Children's Hospital and at Henry Ford Hospital in Detroit, Michigan. He spent one year in industrial surgery and another year on a fellowship in surgery at the Gunderson Clinic in La Crosse, Wisconsin.

* * *

A complimentary dinner at the Minnesota Club on January 19 was tendered Dr. Alexander R. Colvin, Saint Paul, by the surgical staff of Ancker Hospital. A graduate of McGill University Medical School in 1894, Dr. Colvin settled in Saint Paul in 1903 after studying in various European medical centers. He has practiced in Saint Paul continuously since that year, except for his service as a major in the medical corps of the army during World War I. He has been associated with Ancker Hospital since his arrival in Saint Paul, and for the past thirty years has headed the surgical service of the institution.

In his remarks following the dinner, Dr. Colvin urged his audience to re-read the great classics in medical literature and emphasized that all sciences are closely intertwined. He commended the attitude of the Welfare Board in not interfering with the medical work of Ancker Hospital. Stating that the hospital's medical staff ranks with the best in the nation, he said that the institution offers a great field for clinical and pathological study and investigation by young physicians.

Preliminary results of a survey recently conducted by three Minnesota health agencies indicated an enthusiastic interest in the problem of cancer control by Minnesota's practicing physicians.

Conducted by the Division of Cancer Control of the Minnesota Department of Health, the Cancer Committee of the Minnesota State Medical Association, and the state division of the American Cancer Society, the survey showed that (1) most physicians are in favor of a "back to school" movement with expanded continuation courses on cancer research, diagnosis and treatment; (2) half of the physicians who answered the survey advocate a free correspondence consultation service on cancer cases, and (3) two out of three physicians believe in hiring qualified medical men on a full-time basis to travel throughout the state, giving talks on cancer to hospital staffs and local medical societies.

The survey was believed to be the first of its kind on a state-wide basis to ascertain just what practicing physicians and surgeons feel are the best means of fighting the disease. The numerical response to the survey far exceeded expectations.

ship to a town of 550 persons, the community of Bertha.

From numerous candidates throughout the state, Dr. Will was selected as Minnesota's nomination for the AMA gold medal award and his name was presented to the AMA House of Delegates with the backing of the Minnesota State Medical Association.

A graduate of the University of Minnesota Medical School in 1905, Dr. Will began his practice in Bertha immediately after completing his internship. During his forty-one years of practice in the city and the surrounding area, the sixty-eight-year-old physician has attended more than 4,000 births; in September, 1946, many of these "babies" returned to the city to join in a community-wide tribute to Dr. Will.

President of the Minnesota State Medical Association in 1936, Dr. Will is still active in medical and civic affairs. At the present time, in addition to conducting his medical practice, he is president of the Bertha Commercial Club, is busy in Todd County political circles, and is prominent in church work.

* * *

At the annual meeting of the American Academy of Orthopaedic Surgeons, held in Chicago on January 27, Dr. Vernon L. Hart, Minneapolis, presented a paper on "Relationship Between Congenital Subluxation and Congenital Dislocation of the Hip." In association with Dr. Wesley H. Burnham, Minneapolis, Dr. Hart also presented the same subject in an exhibit which was awarded second honors.

* * *

Dr. Henry Michelson, Minneapolis, has been invited to be guest of honor at the annual meeting of the California State Medical Society, to be held in San Francisco in April. Dr. Michelson will discuss cutaneous cancer before the general assembly and will describe the lupus erythematosus problem before the dermatological section.

Dr. Michelson has also been invited to present the postgraduate lectures in dermatology at the University of British Columbia in Vancouver in June.

* * *

Listing of blood types of 2,500 volunteer blood donors among residents of Minneapolis suburban areas was slated to start in Wayzata in late February. Communities taking part in the project, which is sponsored by the Ernest Asleton American Legion Post of Wayzata, are Wayzata, Deephaven, Long Lake and Minnetonka Beach. Plans called for a blood typing center in the Wayzata Legion hall, handling 200 persons a night. The completed listing would enable Minneapolis hospitals to know exactly whom to call to get specific blood type replacements. It was planned to give master donor lists to all major Minneapolis hospitals, physicians' offices, town halls and servicemen's clubs.

HOSPITAL NEWS

New staff officers were elected at meetings held during December and January by the staff members of the following Minnesota hospitals:

Miller Memorial Hospital, Duluth.—At the annual meeting of the medical staff of Miller Memorial Hospital on January 9, Dr. Keith R. Fawcett was elected chief of staff, succeeding Dr. A. J. Spang. Elected

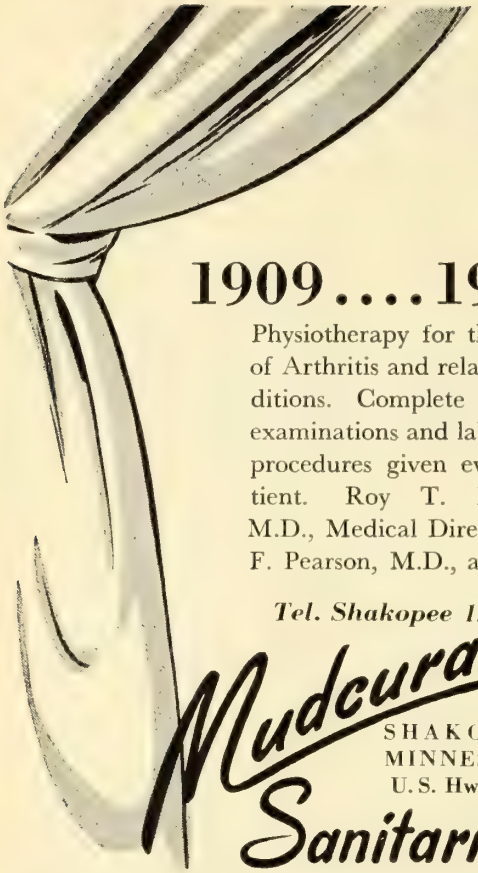
vice chief was Dr. Karl E. Johnson, while Dr. M. G. Fredricks was named secretary. Executive committee members named at the meeting were Dr. Spang, Dr. E. E. Barrett and Dr. Mario Fischer.

Asbury Hospital, Minneapolis.—Dr. Charles H. McKenzie was elected president of the Asbury Hospital medical staff at the annual meeting held late in December. Other staff officers named were Dr. Ann W. Arnold, vice president; Dr. Wayne S. Hagen, secretary and treasurer, and Dr. C. A. McKinlay, advisory board member. Also on the board are Dr. H. E. Hoffert, Dr. Ernest R. Anderson and Dr. R. R. Cranmer.

St. Cloud Hospital, St. Cloud.—Elected president of the medical staff of St. Cloud Hospital was Dr. P. L. Halenbeck, who was named to the office at an election meeting held early in December. Also elected to office were Dr. C. J. Luckemeyer, vice president, and Dr. N. F. Musachio, of Foley, secretary.

St. Joseph's Hospital, Mankato.—New head of St. Joseph's Hospital staff is Dr. H. J. Nilson, who was elected president at the annual meeting of the staff on December 11. Dr. O. H. Jones was named vice president, and Dr. A. A. Giroux, secretary-treasurer. Appointed to the executive board were Dr. A. V. Sohmer, Dr. J. A. Butzer and Dr. Bradley Troost.

Loretto Hospital, New Ulm.—Dr. O. B. Fesenmaier was elected president of the Loretto Hospital staff at a meeting held on January 8. Also named to office were Dr. O. J. Seifert, vice president, and Dr. William Black, secretary.



Union Hospital, New Ulm.—President of the Union Hospital staff is Dr. O. J. Seifert, who was elected to office at a meeting held on January 8. Dr. Carl Fritsche was named vice president of the staff, and Dr. Ted Fritsche, secretary.

St. Joseph's Hospital, Brainerd.—At a meeting on January 8, Dr. W. E. Fitzsimons was named chief of staff of St. Joseph's Hospital, to succeed Dr. J. A. Thabes, Sr. Also elected to office were Dr. G. E. Cardle, vice chief of staff, succeeding Dr. R. A. Beise, and Dr. A. M. Mulligan, secretary-treasurer, succeeding Dr. Fitzsimons.

St. Mary's Hospital, Minneapolis.—Dr. F. B. Mach was elected president of the advisory board of St. Mary's Hospital at the board's annual meeting early in January. Named as vice president was Dr. Leo Culligan, while Dr. L. J. Happe was elected secretary. New members elected to the board were Dr. James Hayes and Dr. Horatio Sweetser.

Included in the recently released 1947 listing of courses approved by the American Dietetic Association is the dietetic internship at the University of Minnesota Hospitals.

The dietetic internship at the University offers supervised application of college training in dietetics. All interns accepted for training are graduates of accredited colleges or universities, with majors in food and nutrition or institution management. The satisfactory completion of a year of postgraduate training in such an approved internship qualifies the student for a position as a hospital dietitian anywhere in the country.

* * *

A continuation course in hospital administration was presented during the week of February 2 to 7 at the University of Minnesota Center for Continuation Study. Co-operating with the University in offering the course were the Minnesota Hospital Association and the American College of Hospital Administrators of Chicago.

The course was divided into two three-day sessions. In charge of the first session, on "Operating Statistical and Accounting Control," was James A. Hamilton, professor of hospital administration. The second session, on "Standards and Methods of Plant Maintenance," was under the direction of James W. Stephan, associate professor of hospital administration.

On the afternoon of February 4, a special general session was given over to a consideration of the survey and construction act, both from the state and national points of view.

TUBERCULOSIS. A Discussion of Phthisiogenesis, Immunology, Pathologic Physiology, Diagnosis and Treatment. Francis Marion Pottenger, A.M., M.D., LL.D., F.A.C.P. Emeritus Professor of Medicine, University of Southern California School of Medicine; Medical Director Pottenger Sanatorium and Clinic for Diseases of the Chest, Monrovia, California. 597 pages. Illus. Price $12.00, cloth. St. Louis: C. V. Mosby Co., 1948.

HERNIA. Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis and Treatment. Third Edition. Leigh F. Watson, M.D., F.I.C.S. Certified by the International Board of Surgery; Formerly Associate in Surgery, Rush Medical College, Chicago; Formerly Assistant Professor of Surgery, University of Oklahoma Medical School, Oklahoma City. 732 pages. Illus. Price $13.50, cloth. St. Louis: C. V. Mosby Co., 1948.

OCCUPATIONAL MEDICINE AND INDUSTRIAL HYGIENE. Rutherford T. Johnstone, A.B., M.D. Consultant in Industrial Health; Lecturer at the University of California, Los Angeles; Formerly Assistant Professor of Medicine, University of Pittsburgh School of Medicine; Formerly Director of Department of Occupational Diseases, Golden State Hospital. 604 pages. Illus. Price $10.00, cloth. St. Louis: C. V. Mosby Co., 1948.

ADVANCES IN MILITARY MEDICINE. Made by American Investigators Working Under the Sponsorship of the Committee on Medical Research. Edited by E. C. Andrus, D. W. Bronk, G. A. Carden, Jr., C. S. Keefer, J. S. Lockwood, J. T. Wearn and M. C. Winternitz; Associate editor Tuckerman Day. 900 pages. Illus. Price $12.50, 2 vols., cloth. Boston: Atlantic Monthly Press, Little, Brown & Co., 1948.

SEXUAL BEHAVIOR IN THE HUMAN MALE. A. C. Kinsey, Professor of Zoology, Indiana University; W. B. Pomeroy, Research Associate, and C. E. Martin, Research Associate. 804 pages. Illus. Price $6.50. Philadelphia: W. B. Saunders Co., 1948.

Even without its well-conducted publicity campaign, this book would be a best seller, because of its title. To compare it to James Thurber's "Is Sex Necessary?" —or call it the medical "Forever Amber" is unfair, as the authors have done a magnificent job in assembling statistical data regarding the sex practices in the human

KALMAN & COMPANY, INC.

Investment Securities

Members:

Chicago Stock Exchange
Minneapolis-St. Paul Stock Exchange

ST. PAUL MINNEAPOLIS

male. The subject has been approached in a frank, honest, intelligent manner. While the subject matter will not be shocking to the physician, the high incidence of the various unconventional sexual practices as reported in this study may be astounding even to him. The authors draw their conclusions from the study of 12,000 interviews. When one realizes how far off the *Literary Digest* was several years ago in picking the winner of a Presidential poll, one may hesitate to put implicit trust in such statistical studies. Also, it is not clear in some instances at what time of life these sexual aberrations took place. Such practices in childhood would have different significance, both moral and physical, as compared to those in adults. Another weakness is the tendency of the authors to rationalize about the statistical data.

As the authors state "The social values of human activities must be measured by many scales other than those which are available to the scientist. Individual responsibilities toward others in the social organization, and the long-range outcome of behavior which represents the individual's response to the stimuli of the immediate moment, are things that persons other than scientists must evaluate. As scientists, we have explored, and we have performed our function when we have published the record of what we have found the human male doing sexually, as far as we have been able to ascertain that fact."

Numerous charts and tables are included in the book. The subject matter is of particular interest to sociologists, psychiatrists and the urologists. All in all, the authors have done an excellent job with a difficult subject.

CHARLES E. REA, M.D.

A PRIMER OF CARDIOLOGY. George E. Burch, M.D., F.A.C.P., Associate Professor of Medicine, Tulane University School of Medicine; Senior Visiting Physician, Charity Hospital; Consultant in Cardiovascular Diseases, Ochsner Clinic; Visiting Physician, Touro Infirmary, New Orleans; and Paul Reasor, M.D., Instructor in Medicine, Tulane University School of Medicine; Assistant Visiting Physician, Charity Hospital, New Orleans. 272 pages. 203 illus. Price $4.50. Philadelphia: Lea & Febiger, 1947.

"A Primer of Cardiology" deals chiefly with the physical diagnosis of heart disease with the subjects of etiology and treatment being outlined only briefly.

Visual education is used and perfected to a high degree. The hemodynamics of normal and abnormal heart sounds are illustrated diagramatically. The timing of the heart sounds and murmurs are visualized by superimposed tracings of carotid pulse wave, venous pulse wave, electrocardiogram and phonogram tracings.

This book is highly recommended for the student and as a refresher in physical diagnosis.

BURTIS J. MEARS, M.D.

THE OCULOROTARY MUSCLES. Richard G. Scobee, B.A., M.D.; Instructor in Ophthalmology, Washington University School of Medicine, St. Louis, Mo. 359 Pages. Illus. Price $8.00. St. Louis: C. V. Mosby Co., 1947.

The author has taken a difficult subject and has covered the field from various angles, preferring to divide the work into five headings and then dividing the whole into twenty-nine chapters. This, at first glance, seems to complicate an already complex subject, but it works out well in the text and when once gone over makes it more satisfactory for subsequent reference.

The author states in his preface that he has adhered to the theory of Chavasse that a paretic muscle will generally regain more of its tonus if its antagonist is weakened, rather than to shorten the paretic muscle, and that the physiological results are improved.

The text has many excerpts and illustrations from current works on ophthalmology. Some chapters seem to have been treated briefly, but in the space of three hundred and fifty pages it would be burdensome to give a more full account, as it would defeat the object of the book.

Bibliographic references follow each chapter and give a ready reference to the specific subject treated in each chapter.

This work represents Dr. Scobee's point of view on the oculorotary muscles. When a man has spent as much time and patience in a difficult field, his viewpoint is worthy of careful attention to those who would be best benefited by a better knowledge of ophthalmology.

J. C. B.

COMMUNICABLE DISEASES. Franklin H. Top, A.B., M.D., M.P.H., F.A.C.P., Medical Director, Herman Kiefer Hospital; Clinical Professor of Preventive Medicine and Public Health, Wayne University College of Medicine; Extramural Lecturer in Infectious Diseases and Epidemiology, School of Public Health, University of Michigan; Consultant, Preventive Medicine Section, Surgeon General's Office, United States Army; and others. 992 pages. Illus. Price $8.50. St. Louis: C. V. Mosby Co., 1947.

The second edition of this highly useful book has been brought up to date in the rapidly advancing field of treatment. Fourteen new chapters have been added which make the book comprehensive in its coverage of

communicable diseases. The author and twenty collaborators have made this a practical book with sufficient detail for treatment of each disease.

The diseases are classified according to portal of entry of the infecting agent, and each disease is discussed as to infectious agent, epidemiology, immunity, pathology, symptoms, complications, prognosis, treatment and prevention. Besides the usual discussion of general topics as immunity, serums, and specific preventions there is an excellent chapter on management of communicable diseases in the home. The chapter on poliomyelitis is especially good.

The illustrations are adequate and the thirteen color plates are above average. The book is recommended for all those who treat communicable diseases.

What About Supply and Demand?

With almost everything today, demand is high and supply is low. And although this well-known economic law is busily working to equate the two, it is often both desirable and possible to hurry the process along.

So it is with nursing. The demand far exceeds the supply. A cooperative effort to increase the supply is currently being made by heads of hospitals, schools of nursing and the doctor. Of the three: *you doctor*—perhaps more than anyone else—can accomplish the most. As a representative of the medical profession, you can best provide the suggestion to prospective nurses in your community. An increased number of trainees must find its way to the nursing schools if the current shortage is to be remedied.

Glenwood Hills Hospitals through its school of nursing, is proud to take part in this effort. Glenwood Hills' graduates have had "care of the patient" and "service to the doctor" stressed to them. In addition to the instruction necessary to perform their duties, they are well equipped with a knowledge of the true purpose of nursing. We respectfully request that you have prospective nurses in your acquaintance investigate our facilities.

FREE ILLUSTRATED BOOKLET

Clip the coupon below and slip it into your appointment book for ready reference. Perhaps you now know of a possible candidate for nurses training. On return of the coupon we will send her an illustrated booklet explaining the school and the training course. She is obligated in no way by this act. It is obvious that more detailed information as to courses and facilities available must be put into the hands of the prospective trainee if nursing is to successfully attract an adequate share of young women. **By giving this coupon to an interested party, you will be assisting materially in the effort to increase the number of trained nurses available to the medical profession.**

It Can Happen Here

Example of severe rickets in a sunny clime.

LEST WE FORGET—we who are of the vitamin D era—severe rickets is not yet eradicated, and moderate and mild rickets are still prevalent. Here is a white child, supposedly well fed, if judged by weight alone, a farm child apparently living out of doors a good deal. This boy was reared in a state having a latitude between 37° and 42°, where the average amount of fall and winter sunshine is *equal to that in the major portion of the United States*. And yet such stigmata of rickets as *genu varum* and the quadratic head are plain evidence that rickets does occur under these conditions.

How much more likely, then, that rickets will develop among city-bred children who live under a smokepall for a large part of each year. True, vitamin D is more or less routinely prescribed nowadays for infants. But is the antiricketic routinely administered in the home? Does the child refuse it? Is it given in some unstandardized form, purchased from a false sense of economy because the physician did not specify the kind?

A uniformly potent source of vitamin D such as Oleum Percomorphum, administered regularly in proper dosage, can do more than protect against the gross visible deformities of rickets. It may prevent hidden but nonetheless serious malformations of the chest and the pelvis and will aid in promoting good dentition. Because the dosage is measured in *drops*, Oleum Percomorphum is well taken and well tolerated by infants and growing children.

OLEUM PERCOMORPHUM WITH OTHER FISH-LIVER OILS AND VIOSTEROL

Potency, 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10 cc. and 50 cc. bottles; and as capsules in bottles containing 50 and 250.

MEAD JOHNSON & COMPANY, EVANSVILLE, INDIANA, U.S.A.

Please enclose professional card when requesting samples of Mead Johnson products to co-operate in preventing their reaching unauthorized persons

THEELIN is a *naturally occurring* estrogen. It is well tolerated and can be administered without significant side reactions or untoward effects.

THEELIN is a *pure crystalline* estrogen. Since it is not a mixture and does not contain extraneous substances, its physiologic effectiveness is accurately determined by weight.

leadership in estrogen therapy

THEELIN is a *highly potent* estrogen. One ten-thousandth (0.0001) of a milligram is equivalent to one international unit. Because of THEELIN's potency, symptoms of the menopause and other estrogen-deficiency states may be readily and effectively relieved.

THEELIN is a *dependable* estrogen. It has stood the test of time. The first estrogenic hormone to be isolated in pure crystalline form and the first to assume clinical importance, THEELIN may be depended on for its reliable and predictable estrogenic effects.

THEELIN is available as **THEELIN AQUEOUS SUSPENSION** in ampoules of 1 mg. (10,000 I.U.), 2 mg. (20,000 I.U.) and 5 mg. (50,000 I.U.);
THEELIN IN OIL in ampoules of 0.1 mg. (1000 I.U.), 0.2 mg. (2000 I.U.), 0.5 mg. (5000 I.U.) and 1 mg. (10,000 I.U.);
STERI-VIAL® THEELIN IN OIL in vials of 10 cc., each cc. containing 1 mg. (10,000 I.U.); and
THEELIN Vaginal Suppositories, containing 0.2 mg. (2000 I.U.).

Watersoaked . . .

. . . and *still* potency-protected!

Four packages of penicillin tablets were recently returned to the Squibb Laboratories. They had been watersoaked to a point of partial disintegration. The outside and inside of the packages were covered with mold — they had been "through the mill". Furthermore, the tablets were outdated by four months.

Yet on assay all but one—39 out of 40—of these tablets were found to be of full potency! (One tablet assayed at 50% of label potency.)

Penicillin is rapidly destroyed by water. It must be produced in an atmosphere scrupulously moisture-controlled. This demonstration of the effectiveness of Squibb packaging methods is therefore highly significant.

CRYSTALLINE PENICILLIN G SODIUM (*Buffered*) TABLETS

SQUIBB

are *individually* and *hermetically* sealed in aluminum foil to protect them against moisture and contamination. They are *individually protected,* regardless of how many are prescribed, up to the time of use. Tablets of 50,000 and 100,000 units in boxes of 12 and 100.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

The First Modern Practitioner

Medicine and Dentistry were rescued from stagnant *generalizations* about disease by the English Puritan, Thomas Sydenham (1624-1689)—just as his ex-pirate assistant, Tom Dover, rescued Robinson Crusoe (Alexander Selkirk).

Sydenham first *observed and described specific and distinct diseases:* scarlet fever, measles, gout, malaria, dysentery, etc. With cool drinks for the smallpox victim, iron for anemia or sedatives for needed rest, he ended a war on *symptoms* and allied the profession with nature—to help the body *heal itself!*

So there were more good doctors in the next century. But the British Common Bench ruled in 1767 that neither their eminence nor good motives were sufficient defense against charges of malpractice or negligence; that a patient yielded no rights in submitting to treatment; that definitions of "skill" and "due care" varied with circumstance.

Doctors Since 1899 have not had to rely solely upon the inadequate defenses of eminence or good motives. They have safeguarded their time, money and reputations with The Medical Protective policy—for *complete* protection, *preventive* counsel and *confidential* service.

PICTURE OF how B. J. Bender became a nutritive failure....

Bender is but one of the great American army of chair-warmers, shining examples of the need for two-pants suits. Exercise? They lie down until the thought of it passes. Appetite? They seek the bizarre in food to goad their tired taste buds. Result? In too many cases, sub-clinical vitamin deficiency—a condition in which the sedentary worker has a host of companions in nutritional crime: the food faddists, chronic dieters, excessive smokers, alcoholics and many others. Dietary reform is the physician's first thought, of course—vitamin supplementation usually the second. And the vitamin preparation specified very often carries the "ABBOTT" name. There is a wide variety of vitamin preparations available in the complete Abbott line . . . for oral and parenteral use . . . for almost any patient's needs, age or taste. If you are not already familiar with Abbott's dependable vitamin products, they are worth your investigation—and trial. ABBOTT LABORATORIES, NORTH CHICAGO, ILLINOIS

Abbott Vitamin Products

Experience is the Best Teacher

It's true in medicine—

John William Ballantyne

(1861-1923)

proved it in obstetrics

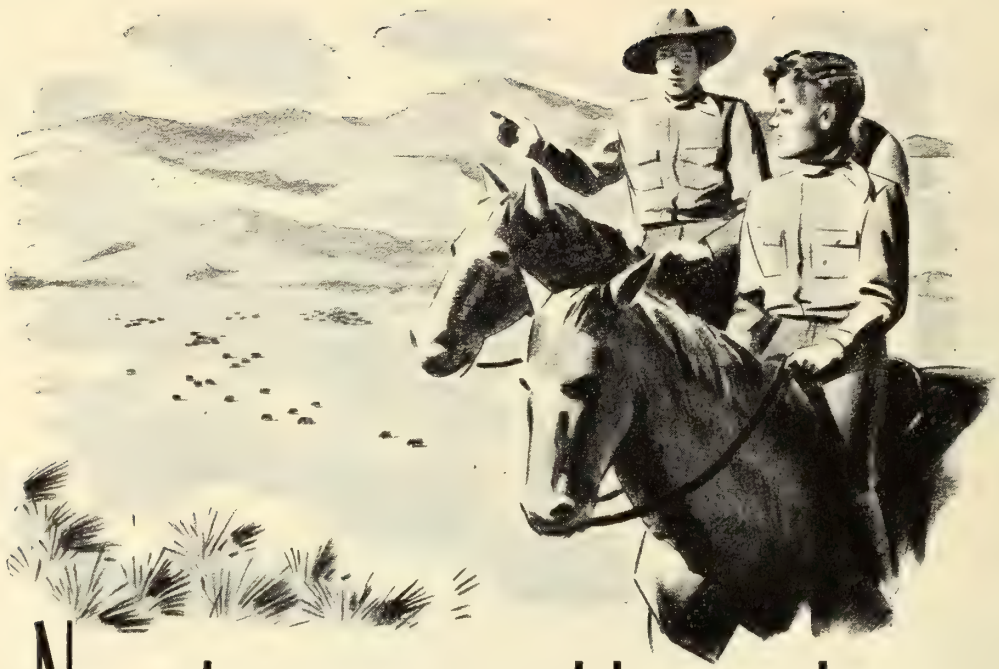
BALLANTYNE, in his early studies of anatomical and pathological conditions found in the new-born, sensed the value of routine prenatal care in obstetrics. As a pioneer for prenatal care he was the first to establish a clinic for the expectant mother. World-wide acceptance of Ballantyne's concepts quickly followed his successful experiences in prenatal supervision.

Experience is the best teacher in choosing a cigarette, too!

MORE PEOPLE ARE SMOKING CAMELS THAN EVER BEFORE!

Yes, experience *is* the best teacher in choosing a cigarette. Millions of smokers who have tried and compared different brands have found that Camels suit them best. As a result, more and more people are smoking Camels as the "choice of experience."

Try Camels. See if your own taste doesn't appreciate the rich, full flavor of Camels. See if your own throat doesn't welcome Camel's cool mildness.



Let your own experience tell you why more people are smoking Camels than ever before.

According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

When 113,597 doctors from coast to coast — in every field of medicine — were asked by three independent research organizations to name the cigarette they smoked, more doctors named Camel than any other brand!

No other crop could grow here

Vast areas of the country would have to be considered wasteland, so far as human nutrition is concerned, were it not for the ability of livestock to feed on the grasses and roughage growing in the many areas which do not lend themselves to cultivation.

Our livestock population turns many plants, in themselves inedible by man, into meat . . . man's preferred protein food.

Thus livestock makes land, which otherwise would be useless for human nutrition, produce an outstanding protein food for man. This is of added importance today because of the world-wide scarcity of high-quality protein foods.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

FOR EFFECTIVE PROPHYLAXIS OF DRUG REACTIONS

PYRIBENZAMINE

In the prophylaxis and treatment of allergic reaction to liver extract, penicillin, the sulfonamides and certain other drugs, Pyribenzamine hydrochloride is definitely efficacious.[1,2]

Similarly, the administration of Pyribenzamine prior to a desensitizing dose of allergen is successful in the prevention of constitutional reactions.[1] By using Pyribenzamine routinely during desensitization therapy, it is possible to make greater increments of dosage, thereby reducing the total number of injections.[3]

in Infancy

when public allergy number 1 is

Milk

Cow's milk heads the list of "worst offenders" in infant diet allergies.[1, 2] Obviously, "when one or more of the so-called essential foods are at fault, adequate substitutes must be provided if the symptoms are to be relieved and proper nutrition be maintained."[1] In all milk allergies (which may persist through infancy into childhood and even adulthood), MULL-SOY affords an ideal replacement. Completely free from offending animal proteins, it supplies a rich vegetable source of all the vital amino acids. Indeed, in standard dilution (1:1), MULL-SOY very closely resembles cow's milk in its percentages of protein, carbohydrate, fat and mineral content; and as a calcium source is comparable in every way with milk.[3] It is palatable, easily digested, and well-tolerated by every age.

ACCEPTED COUNCIL ON FOODS AND NUTRITION AMERICAN MEDICAL ASSOCIATION

MULL-SOY is a liquid hypoallergenic food prepared from water, soy flour, soy oil, dextrose, sucrose, calcium phosphate, calcium carbonate, salt, and soy lecithin; homogenized and sterilized. Available in 15½ fl. oz. cans at drugstores everywhere.

middle age + verve

Verve or apathy in middle age? For the menopausal patient this is usually determined by the degree of relief from the distressing symptoms so often associated with declining ovarian function.

Gratifying and prompt remission of disturbing symptoms may be obtained with ***"Premarin."*** *Outstanding among comments made by patients receiving this naturally occurring, orally active estrogen, is the reference to the "plus" that changes apathy into action...the "sense of well-being" following therapy which is so much appreciated by the middle-aged woman who wants to live usefully and enjoyably.*

While sodium estrone sulfate is the principal estrogen in ***"Premarin,"*** *other equine estrogens...estradiol, equilin, equilenin, hippulin... are probably also present in varying amounts as water soluble conjugates.*

Three potencies of ***"Premarin"*** *enable the physician to fit the dosage to the individual needs of the patient: 2.5 mg., 1.25 mg. and 0.625 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).*

Conjugated Estrogens (equine)

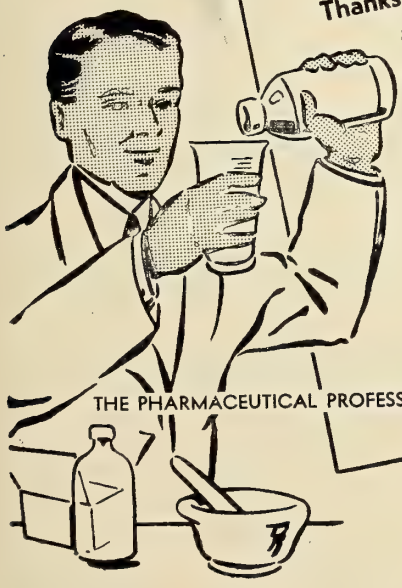
SPONSORS of our Maturity



THE MEDICAL PROFESSION

"GROWING UP" implies far more than gaining height and adding years. It means acquiring competence, assuming responsibility, forming a circle of friends, attaining maturity.

In the forty years from 1908 to 1948, The Smith-Dorsey Company has been steadily "growing up"—but not by our own efforts alone.

Our growth has been sponsored by our constantly growing circle of friends in the medical and pharmaceutical professions.

Thanks to your loyal encouragement and patronage, we are today able to repay our sponsors with excellent service and high standard products assured by a new research and manufacturing plant . . . increased research grants . . . added research personnel . . . two new branch offices and shipping warehouses . . . added medical service representation.

DO YOU KNOW WHAT THESE SYMBOLS STAND FOR?

Rexall
DRUGS

You can depend on any drug product that bears the name Rexall.

Noah was in at the birth of this symbol. Since, in almost all lands, it has come to mean one thing: Hope. See a rainbow in the sky and you see a promise of days less laden with trouble.

The familiar Rexall sign is a modern symbol: Up and down the land, displayed proudly by about 10,000 independent and reliable drug stores, it signals an important message to the millions. Here is a symbol, it says, that assures the highest pharmacal skill in compounding your prescription. It means, further, that all drugs used are potent, pure and uniform . . . all laboratory tested under the rigid Rexall control system.

A new antibacterial agent

for your most resistant cases of wound and surface infections

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

Contains 0.2% Furacin (brand of nitrofurazone: 5-nitro-2-furaldehyde semicarbazone) in a water-soluble base.

O_2N $CHNNHCONH_2$

another of its several advantages:

FURACIN SOLUBLE DRESSING *has proven effective* in reducing the mixed infections of wounds and burns. Prior to treatment, Snyder et al.* found heavy growth in the majority of swab-cultures from 19 war wounds and burns. Following institution of Furacin Soluble Dressing therapy, the majority of cultures became sterile; only 4 per cent continued to show heavy growth.

Indications:

Infected surface wounds, or for the prevention of such infection
Infections of second and third degree burns
Carbuncles and abscesses after surgical intervention
Infected varicose ulcers
Infected superficial ulcers of diabetics
Impetigo of infants and adults
Treatment of skin-graft sites
Osteomyelitis associated with compound fracture
Secondary infections following dermatophytoses

CO-OPERATION BETWEEN THE PHYSICIAN AND THE CANCER SOCIETY

A. E. CARDLE, M.D.

President, Minnesota State Medical Association
Minneapolis, Minnesota

THE common aim of both the medical profession and the American Cancer Society is cancer control. The society has certain means with which it hopes to aid in this control. The medical profession also has certain ways in which it hopes to aid. There must, of course, always be the most friendly understanding between these two as to methods and policies. For after all, the "control of the disease" is the goal to be achieved, and all ideas must point to this goal. I wish, therefore, to point out briefly the progress which is being made in this fight for cancer control.

Cancer control today is fortunately not the hopeless problem that it was a few years ago, and the untiring efforts of the American Cancer Society are contributing substantially to the progress being made. This organization, with all of its component parts, can take just pride in the fine record of achievement it has made since its founding in New York in 1913, while realizing that the task which lies ahead for it is still an infinitely challenging one.

The society's three-pronged attack on the disease—research, education and service—is doing much to dispel the gloomy atmosphere that has surrounded cancer, and to replace with hope the pessimism with which this disease has been regarded in years past. The American Cancer Society now has a permanent national program for educating the general public on cancer. This program is recognized and fully approved by the medical profession. Intensive educational campaign in the various types of cancer, such as cancer of the breast or of the uterus, are bearing fruit as more and more women become alert to the danger signals and seek help in time. Literature, films, exhibits and speakers have been provided on a broad scale. The medical field representatives of the society are moving about the country stimulating and directing local interest and activity wherever their help is desired. This is of utmost importance. The society's program was formally endorsed by the House of Delegates of the American Medical Association in December, 1945. Noteworthy is the fact that the society has always worked in close co-operation with the medical association—at the national, state and local levels. All of its literature is either prepared or carefully scrutinized by fully qualified medical authorities. Its projects have always been closely supervised by doctors, and all programs have medical approval before they are instituted.

The medical profession is also battling this disease on a steadily increasing scale. Cancer committees of state and county medical societies have been organized to help with educational work among medical men. The Minnesota State Medical Association appointed a cancer committee in 1919 and continues to maintain it. The importance of the cancer committee of the state medical association cannot be overemphasized. In several states, including our own, the cancer committee has prepared scientific booklets and pamphlets for distribution to practitioners to acquaint them with the latest methods of cancer diagnosis and treatment. This activity, in turn, has helped to change many a doctor's attitude toward the disease.

Much credit is due members of the Women's Auxiliary whose unceasing efforts in the field of cancer education are producing especially encouraging results. Much of the work carried on

Read at the annual meeting of the Minnesota Division, American Cancer Society, January 20, 1948, University Campus, Minneapolis.

by these women is directed at children of school age, and I believe everyone would agree that if fullest public co-operation in the battle against cancer is to be attained in the future, it must stem to a large degree from properly educating now the children who will be tomorrow's citizens.

Another group having a tremendous influence for good in the cancer fight is the American College of Surgeons. This body has demonstrated the genuine desire which the medical profession has generally, that is, to co-operate with other responsible groups in the cancer control field and to see that the highest possible standards are maintained in the care and treatment of cancer patients. Through the efforts of the American College of Surgeons, cancer clinics with qualified personnel and adequate equipment are being established throughout the country. Starting with only a few such clinics, there are now well over 400. The College inspects them and approves only those maintaining established standards. The educational effect of this practice is very noticeable. People today demand better and more thorough examinations and more careful diagnosis in cases of suspected cancer than they ever did before these high-type cancer clinics were established.

The nature of cancer has an important bearing on the type of control program that can be carried on. Not only must the disease be fought, but so must fear of the disease, which in uninformed or partially informed minds can and often does approach terror. Because of this deeply rooted fear of cancer, any facts which are released concerning the disease must be presented very impersonally, yet, at the same time, the facts themselves—the symptoms of the disease, its diagnosis and treatment—are of a highly personal nature. Confidence must be built up in the minds of the public, and yet hopes must not be raised unduly. Truth and only truth must be presented, but it must be presented from the positive, optimistic angle. Here, doctor and lay worker have an obligation to co-operate fully for best results. There must be complete understanding on the part of both doctors and patients of the relative merits of surgery and radiology in cancer therapy—overenthusiasm for one must not be allowed to overshadow the other. The need for careful and accurate physical examination, whether cancer is or is not suspected, is vital. Superficial diagnoses must not be tolerated, and they can most quickly be abolished when an intelligent lay public spurs the medical profession to put forth its best efforts.

Cancer education would be meaningless without facts with which to work. These facts are brought to light, one by one, in scores of countless laboratories by painstaking research workers. During the war we became aware of the life-saving potentialities of scientific research. Penicillin, sulfas, dried blood plasma and other wonders were rushed from the laboratory to the firing line, where they helped to save thousands of young men who would otherwise have died. Today, research in cancer faces a future of limitless possibilities. For example, research has shown how to produce and control the disease in laboratory animals. It has revealed also the difference between the normal cell and the cancerous one. Support for this all-important research is badly needed. Fortunately, several organizations including the American Cancer Society are extensively supporting cancer research, for cancer research needs financial support and trained workers. More substantial support of the cancer laboratory will pay big dividends in probing cancer's secrets, and the only way we can ever conquer cancer is to learn *all* of its secrets.

Here in Minnesota, where cancer claims over 4,000 lives annually, several research projects are being developed. Recently approved by the medical Association was the establishment of a Tumor Registry and Statistical Research Service at the Minnesota Department of Health. This project was created to fill the need for more information on the general cancer picture in the state. Up to the present time, the only statewide record of this disease has come from reports of cancer deaths to the division of vital statistics. Much valuable information on cancer cases, living and dead, is available from hospital records. In the hope that comprehensive information about cancer in Minnesota will lead to better understanding of the problem, the Cancer Control Division of the State Health Department is planning, by means of the tumor registry, to carry out a statewide statistical study of the cancer situation in Minnesota and to supply the medical profession of the state with all the available data. This will include information regarding the incidence, types, forms of treatment, facilities available for diagnosis and treatment, results of different types of treatment, and so on.

It is contemplated to carry out this study for a period of years by collecting data from reports of cancer cases by hospitals, clinical pathologists and dermatologists. The Minnesota Hospital Association has pledged to support the project. Hospital record librarians will co-operate in assembling the data. Clinical pathologists will be requested to send in copies of reports on tissue examinations which are positive for cancer. Reports of autopsies on cancer cases will be obtained, if possible, from hospital records. Skin specialists will be asked to report on cancer cases seen by them, since such cases often do not enter the hospital. In all, every attempt will be made to obtain as complete data as is possible.

The legal liability of a physician or hospital in giving information which might be considered privileged has been raised. The attorney general has ruled, however, that the health department can require such reports, thus exempting the physician and the hospital from responsibility. In the project, the health department will employ experts to file and interpret the data. Every modern device will be employed for filing and analyzing the material in the reports, and when assembled, it is planned to publish the findings and make the information gleaned from the project available to the medical profession of the state.

Cancer has often aptly been described as a silent disease in its early stages, since all too often cancers go undiscovered until too late. Here, then, is another challenge for the field of research: to seek methods which may detect earlier than otherwise not only cancer but precancerous conditions or areas of chronic irritation which might lead to cancer. That is the idea behind the formation of the cancer detection center. At the cancer detection center a group of apparently well persons will be furnished a prescribed physical examination with special emphasis on conditions which might become cancerous. These people, all over the age of forty-five, will be studied and observed over a certain period of time. A sharp rise in the frequency of cancer occurs in men and women after this age. Therefore, if patients forty-five or over are selected for study, it is entirely possible that much valuable information may be obtained. It is of prime importance that the persons selected for study be in apparent good health. This is only logical, since the persons most often claimed by cancer are apparently well—until it is too late.

In establishing standards for approval of cancer detection centers, the American College of Surgeons and the American Medical Association agreed that there should be definite limitations on what a detection center could do. It was decided that a detection center should concern itself primarily with investigation and research and that it should not treat patients. Therefore, each person is given a thorough physical examination with particular attention to conditions or areas which might develop cancer. When cancer is discovered, the patient is referred to his own family doctor, who is given a complete report on findings at the center. Establishment of such a center is a tremenrous forward step, and its success, of course, will depend upon the attitude and cooperation of all people involved.

The patient himself is the first line of defense against cancer. It is up to him to know the danger signals and to seek help when they appear. At this point, tactful education, such as is carried on so splendidly by the American Cancer Society, makes its greatest contribution. Only the prospective patient can recognize the danger signs, and he must therefore be the person to report his suspicions to his doctor. Proper education will not only counteract fear and dread but also the false modesty which for some women has proved an ally of death. In the past, persons have avoided medical aid until the deadline for saving their lives is past, for fear of being laughed at for their suspicions, or of being called a "cancer phobe"; for fear of embarrassing examinations, fear of learning the truth, desire to avoid worrying the family, fear of doctors and of maiming illness, fear of surgery. Doctors can do much to combat these emotional reasons. A friendly, helpful attitude on the part of the examining physician will do much to reassure a timid or distressed patient.

Fears also arise from economic reasons—inability to meet the cost of medical care, financial obligations to dependents, fear of losing a job. Lack of funds need not discourage a patient from seeking competent medical service, for all physicians of recognized ability give due consideration to the financial situation of the patient, and all reputable hospitals regulate their charges accordingly.

Finally, there are those people who delay their visit to the doctor because of a lack of knowledge

about cancer: they have no pain, they can go on working, hence they cannot be sick. Or perhaps their cancer resembles some common ailment like a cold sore or a case of eyestrain. Then, too, they may have interpreted their own symptoms and may be treating them with the help of family, friends, home remedies, patent medicines—or, even worse, they may have fallen victim to a cancer quack, of whom there are many, I am sad to say. Under no circumstances is it wise to select for treatment of cancer a person who advertises a cure for cancer or demands that a fee be paid in advance, or who is not willing to call another physician in consultation when necessary. Such methods are not practiced by reputable medical men. In view of the seriousness of every cancerous conditions and the frequent rapidity of its progress, it is criminal to waste valuable time and money by trifling with unscientific remedies or nonmedical persons who are not competent to treat this disease.

Thus the patient is the first line of defense against cancer. The second line of defense is the physician. The medical profession is recognizing more and more its heavy responsibility to strengthen our defenses against all cancer. The medical association of our state and those of several other states have published manuals for physicians containing scientific facts on cancer and have attempted to stimulate interest in the disease by conducting lectures and short postgraduate courses on cancer. Even though health education in cancer is making people "cancer conscious," it is recognized that the patient cannot diagnose or cure his own cancer. All one can do is watch for the signs and consult a physician immediately if any such signs appear. From that time on, assuming the patient is co-operative, the responsibility rests upon the physician.

Now it is all very fine and impressive for the members of the medical profession to work together to educate the public and to support cancer control collectively. But after all, it must be admitted that the family physician to whom the patient will probably go first is the No. 1 man on the firing line. The saving of cancer patients is dependent on keen observation and knowledge on the part of the practitioner, not the surgeon or specialist. The family doctor must read the signs and take appropriate action, or refer the patient to someone who can. The medical profession is not quite content with telling the public what ought to be done. It has also made certain through its journals, meetings and postgraduate courses that doctors have every opportunity to prepare themselves to render the best possible service to their cancer patients through the possession of up-to-date knowledge and techniques. Here is where the doctors not only co-operates best with the cancer society, but where he lives up to the ideals of medicine.

There is a third line of defense against cancer—and it is highly important, for without it, the other two defenses, important as they are, will be worthless. This final line of defense is the doctor trained in pathology, surgery or radiology —the man who can actually eradicate cancer from the human body. Accurate diagnosis is of no avail without competent treatment.

Altogether, the recent trends in cancer mortality are encouraging and there is reason to believe that real gains are being made, that cancer deaths are beginning to come under some control. During the past ten years, noticeable progress has been made, particularly among women. The educational campaign is progressing rapidly and with good results. Here in our state the Minnesota Division of the American Cancer Society maintains an excellent information service. Last year, as one indication of the public interest stimulated by the Minnesota Division, there were received 900,000 actual requests for information on cancer, which were filled by the Division. The Minnesota Division has also been working through the schools and has printed a study outline on cancer for secondary schools, which is correlated with the State Education Department's health education course. It is entirely optional, but students are becoming interested, as evidenced by the 16,000 requests for cancer information from high school students received last year.

Steadily increasing control over cancer may be attributable to other factors of education. The close relation, for example, between cancer of the cervix of the uterus and neglected birth injuries is recognized. Improved obstetrical and maternity care is undoubtedly greatly reducing such cancers among women. Similarly, attention to mouth hygiene is reducing cancers of the mouth. But far more important in the total picture is the constantly increasing number of physicians trained to deal effectively with the disease, the marked increase in public and private facilities

(Continued on Page 258)

VAGOTOMY IN THE TREATMENT OF IDIOPATHIC ULCERATIVE COLITIS AND REGIONAL ENTERITIS

CLARENCE DENNIS, M.D., FRANK D. EDDY, M.D., and DARRELL WESTOVER, M.D.
Minneapolis, Minnesota

AS one of us reported to the Minneapolis Surgical Society three years ago, the proper application of surgical therapy to idiopathic ulcerative colitis at the University of Minnesota Hospitals in the years 1934 to 1944 resulted in a drop in mortality rate from 28 to 8 per cent. The figure of 8 per cent has not changed appreciably since that time, and the great majority of the survivors of ileostomy and colectomy have been restored to good health. About one-third of them in the past three or four years also have regained use of the rectum by ileoproctostomy.

Although the over-all figures appear fairly satisfactory, and most of the patients return to active work, one cannot help being impressed by: (1) the radical nature of the surgery needed; (2) the deforming consequences thereof; (3) the psychic trauma thus inflicted on already somewhat unstable personalities; (4) the occasional annoying complications of partial obstruction at the ileostomy, ascending ileitis, and skin erosion by the ileostomy discharge, and (5) finally, the occasional surgical catastrophe which still we cannot escape entirely.

In view of these considerations, a simpler and more fundamental approach to the problem is needed. Various measures have been suggested. Bargen's vaccine has helped in some cases; streptomycin by mouth has appeared to bring marked temporary improvement in a few; sulfathaladine has been disappointing; folic acid, in the hands of Dr. Marcus Keil of the Department of Medicine, has been of little help; and use of tetraethyl ammonium bromide, in the hands of Dr. Russell Wilson of the Department of Medicine, has had an adverse effect in five cases out of seven studied. We were aware of the work of Laurence Martin, but have not as yet employed thiouracil.

Employment of division of the vagus nerves was precipitated by the case of a twenty-year-old girl who previously had all her colon and five-sixths of her ileum removed for severe idiopathic ulcerative colitis and ascending enteritis. Severe recurrent enteritis in the remaining six feet of intestine in October, 1946, demanded some active therapy after all known conservative measures had failed. Vagotomy was suggested by Dr. C. J. Watson, chief of the Department of Medicine at the University of Minnesota. In combination with a revision of the ileostomy, it resulted in the first solid stools she had had in four years, weight gain, and a temporary return of moderately good health. Unfortunately, her condition had become critical during operation, and the chest had to be closed hastily and without performing a complete vagotomy. The improvement was temporary, and, therefore, in September, 1947, several large additional vagus fibers were resected. No definite improvement seemed to follow this second procedure. She remains a problem, with abdominal cramps and some ileostomy difficulties due to the high intestinal secretions.

Employment of vagotomy for cases of idiopathic ulcerative colitis not previously subjected to operation seemed in order. Four such cases, all of very low grade, were subjected to vagotomy in the last three months of 1946. No further divisions were done for six months in order that rather careful evaluation might precede the use of the procedure in any larger group of patients. Symptomatic relief in these four cases and the finding of normal proctoscopic appearances led to the routine application of vagotomy to all available cases of idiopathic ulcerative colitis and regional enteritis, on the supposition that only by fairly wide trial could the method be fairly evaluated.

Transthoracic vagotomy has been employed routinely in fear of aggravation of the disease through handling of the colon by employment of the subdiaphragmatic approach. Recollecting a cancer incidence of some 12 to 13 per cent in patients having had the disease more than five years, we have been careful to exclude this complication by thorough roentgen and proctoscopic studies. In one case, a subdiaphragmatic approach was

From the Department of Surgery, University of Minnesota Hospitals, and the Department of Surgery, Minneapolis General Hospital. Supported by a Research Grant from the Graduate School of the University of Minnesota, by the Patients' Fund for Clinical Research, and by the George E. Durkee Fund for Surgical Research.

Presented before the Minneapolis Surgical Society, December 4, 1947.

used because other studies had not been convincing.

As of the present time, twenty-three patients in this series have had vagotomy performed. One developed cardiac arrest on the table and recovered only after cardiac massage and conversion to ventricular fibrillation, in turn controlled with procain; she died nine days later, apparently of myocardial infarction. Of the remaining twenty-two, one patient had only a functional diarrhea; three had regional enteritis in addition to ulcerative colitis; four had had previous ileostomy and colectomy and had vagotomies for ascending enteritis or disease in the remaining rectum; two had had pervious colectomy and ileoproctostomy; two had had ileostomy only, and one had had ileostomy and partial enterectomy with simple closure of the ileostomy at the time of the vagotomy.

As Table I indicates, three patients have been operated upon too recently to allow evaluation. Two of the nineteen patients, followed a month or more, are worse. One of these had a lead-pipe colon resulting from fourteen years of disease; his stools have increased from eighteen a day to twenty-five a day. The other had had his ileostomy and colectomy elsewhere, and had a vagotomy performed in the false hope that an active proctitis might subside.

Fourteen of the nineteen patients have had definite improvement, and five of these fourteen have become entirely asymptomatic.

The most striking case is that of a boy of nineteen with a five-week history of diarrhea and septic fever and a loss of 58 pounds over a longer period. Roentgen study had shown not only diffuse colitis, but also regional enteritis involving the jejunum and the ileum. The stools numbered eight to twelve a day. Following three days of preparation, vagotomy was done. There were two stools in the next four days, and he became afebrile in forty-eight hours and has remained so. He has gained over 30 pounds in the two and one-half months since operation, now has one formed stool a day, and, as the barium enema shows, the colon has improved vastly. Studies on the small bowel have been difficult to do because of slow emptying of the stomach and the virtual impossibility of intubation of the duodenum after vagotomy; but they nevertheless show marked improvement also.

TABLE I. VAGOTOMY IN IDIOPATHIC ULCERATIVE COLITIS

Type of Surgery	Result				Totals
	Worse	Same	Improved	Asymptomatic	
Vagotomy alone	1	2	5 (a)	4 (bc)	12
Vagotomy plus:					
(1) Previous ileostomy and colectomy	1 (d)	1	2 (e)		4
(2) Previous colectomy and ileoproctostomy			1	1 (c)	2
(3) Previous ileostomy and partial enterostomy, and closure of ileostomy with vagot.			1		1
Totals	2	3	9	5	19

There has been one surgical death; 3 cases are too recent to evaluate. (a) One case of functional diarrhea. (b) Amebae found in one case. (c) One case Crohn's disease plus ulcerative colitis. (d) Increased disease in remaining rectum. (e) Gastroenterostomy required in one case.

In general, the best clinical results have followed vagotomy in cases of short duration or with mild demonstrable fibrosis. The rationale of vagotomy in this disease is based on the demonstration of Rolf Lium that postganglionic sympathectomy in dogs is followed by lesions suggesting clinical colitis in man, and on the marked relief of gastrointestinal spasm observed by L. R. Dragstedt to follow division of the vagi for duodenal ulcer. Extensive laboratory studies by Wangensteen, Friesen, and Lillehei have failed to demonstrate any abnormality in digestive enzymes in these cases or any changes in enzymes or motor activity of the ileum following division of the vagi in dogs. Prudden and associates have, however, shown changes in lysozyme activity in colitis.

Clinical studies on candidates for vagotomy have been carried out preoperatively, during the patient's postoperative hospital stay, and in half the cases some three or more months later. Fur-

ther studies are in progress. The studies include gastrointestinal stasis x-rays, charcoal transit times through the intestinal tract, barium enema, proctoscopic examination, histamine gastric analysis, Hollander insulin test for gastric secretion, twelve-hour (overnight) gastric suction specimen, electrocardiogram, and a chart record of stools as to amount, character, and content of blood, pus, or mucus, both by gross appearance and by laboratory examination.

Gastrointestinal studies postoperatively have displayed marked slowing in gastric emptying, the stomach rarely being empty of barium in twenty-four hours and usually containing a trace or more at forty-eight to seventy-two hours. Our stasis studies also indicate prolongation of intestinal transit, even when gastric emptying begins immediately.* The same has been true in two patients subjected to study in connection with vagotomy for duodenal ulcer. Roentgen observations on the status of the small bowel as to active disease or changes in the mucosal pattern have not been entirely satisfactory. In three cases with well established regional enteritis (pathological, or proctoscopic demonstration after ileoproctostomy), only one was demonstrated by radiological techniques.

Four patients have improved from a radiological point of view to such a point that the barium enema shows no abnormality. Proctoscopic examinations have shown marked improvement in a majority of patients, in some showing striking improvement within two weeks after operation.**

The triple-histamine gastric analysis has been routine throughout most of this study. In two patients, vagotomy was followed by total loss of free hydrochloric acid response to triple histamine. Most of the others responded to vagotomy with a considerable drop in response to histamine.

By means of the Hollander insulin test for gastric acid secretion, we had postoperative evidence in three cases that section of the vagi was incomplete. One of these was the first case in this series, and she had to have a second vagotomy. The other two patients are symptom free.

Twelve-hour gastric specimens have not been consistent. Nine patients have shown marked reduction in volume. The rest have remained unchanged or have increased slightly, with one exception. In this instance, the patient developed gastric retention, necessitating gastroenterostomy. The hydrochloric acid levels compare in general with the findings of Dragstedt, Grimson, Moore, Walters, and others in their vagotomy series for ulcer of the stomach and duodenum.

Electrocardiograms in most instances have been unchanged by operation. In three instances minor changes occurred; in one a marked tachycardia occurred; and in one, cardiac arrest occurred with the start of manipulation of the mediastinum.

The charcoal transit time has been reguarly prolonged after vagotomy. Eight patients who showed blood, pus, or mucus, or combinations of these findings preoperatively, have stools entirely free of them after vagotomy. The tendency has been toward more formed stools, particularly in the early cases in whom no other surgery had previously been performed.

Conclusion

Vagotomy has been undertaken in twenty-two cases of idiopathic ulcerative colitis and in one case of functional diarrhea. One patient died of cardiac complications without completion of the vagotomy. Two patients are definitely worse, three are unchanged, fourteen have improved, and three have not been operated upon long enough for evaluation. Two of the excellent results occurred in patients also suffering from regional enteritis.

Patients with longstanding disease and those presenting much fibrosis of the bowel wall seem to have done less well than those in the acute phase and those having good bowel elasticity. This is perhaps fortuitous in view of our high cancer incidence in the older patients. We still cannot unerringly discriminate which patients will be unchanged or injured by division of the vagus nerves. It should once again be emphasized that vagotomy should not be employed promiscuously, but only where serious study and evaluation of the method are the aims.

*The authors wish to express their thanks to Dr. L. G. Rigler and the members of his department for their interest and help in the execution of these studies.

**The authors wish to thank Dr. William C. Bernstein, Dr. Howard Frykman, and Dr. Victor Swanson for their interest and co-operation in performance of the proctoscopic examinations.

GASTRIC NEURECTOMY (VAGOTOMY) IN THE TREATMENT OF DUODENAL ULCER

Anatomic Considerations

WILLIAM F. BRADLEY, M.D.
Rochester, Minnesota

AN ANATOMIC investigation of the course and distribution of the right and left gastric nerves has recently been completed. According to Cunningham,[1] "the two vagus nerves, after forming the posterior pulmonary plexuses, descend to the esophagus, where they form with each other and with branches of the sympathetic, the esophageal plexus. From this plexus, two nerves pass downward, one on the front and one on the back of the esophagus, through the opening in the diaphragm. Each of these nerves contains fibers from both vagi, and they are termed the *anterior and posterior gastric nerves.*" Hereafter in this paper, the term "right gastric nerve" will replace the term "posterior gastric nerve" and the term "left gastric nerve" will replace the term "anterior gastric nerve." This is done because, in our observations, the right nerve was not always posterior and the left nerve was not always anterior in position.

The results presented herein are based on 100 dissections made at necropsy. The results of eleven additional dissections made on the bodies of children were not included. Although the course and distribution of the gastric nerves in these eleven instances did not differ from that found in the bodies of adults, the results were not included in the statistical analysis because of the uncertainty, at the beginning of the dissections, of the accuracy of observations made on small nerve trunks. These 100 dissections were made on the bodies of fifty-six men and forty-four women whose ages had ranged from twenty-four to eighty-four years.

Generally speaking, it was observed that the gastric nerves arose from the esophageal plexus at about the level of the bifurcation of the trachea. The right and left gastric nerves coursed caudad and, generally speaking, ultimately terminated on the stomach. There were, however, certain qualitative variations that permitted classification of the dissections into four groups.

In 92 per cent of the 100 dissections, the gastric nerves took origin from the esophageal plexus on the anterior wall of the esophagus behind the bifurcation of the trachea and behind the main bronchi. As the gastric nerves coursed caudad, many intercommunicating branches between the right and left trunks were observed. Furthermore, small fibers that coursed anteriorly and inferiorly over the vertebral column and the aorta were added to the gastric nerves. Sometimes intercommunicating branches were seen to enter the musculature of the esophagus and either lose their identity or emerge onto the anterior surface of the esophagus at some more caudal position. By the time the nerve trunks and branches had reached the esophageal hiatus, a relatively large trunk had been formed. These trunks passed through the esophageal hiatus into the abdomen.

The ninety-two dissections just referred to constituted three of the four groups. The first group (64 per cent of the 100 dissections) was characterized by the fact that all of the branches between the gastric nerves and from more remote sites joined to form common trunks on the right and left sides of the esophagus somewhere between the superior aspect of the diaphragm at the esophageal hiatus and 6 cm. above the diaphragm.

In the second group of dissections (7 per cent) there were so many intercommunications between the main trunks of the gastric nerves that a plexus was formed on a major portion of the anterior surface of the esophagus.

The third group of dissections (21 per cent) was characterized by the fact that the long discrete trunks had neither additions of fibers nor intercommunications below a point 6 cm. above the diaphragm.

In the fourth group of dissections (8 per cent) any consistent or uniform course or pattern was not found. In some instances, well-formed trunks were evident from which, somewhere near the diaphragm, a well-defined branch left a main trunk, coursed laterally in the thorax and became lost before leaving the thorax. Another variation was that of a failure of the numerous branches of

---

From the surgical service and under the direction of Dr. Waltman Walters with assistance from Drs. J. T. Small and J. W. Wilson. Dr. Bradley is a Fellow in Medicine at the Mayo Foundation, Rochester, Minnesota.
Read at the meeting of the Southern Minnesota Medical Association, Faribault, Minnesota, September 9, 1946.

the esophageal plexus to form into a common trunk on one or both sides. Under such circumstances, the multiple small fibers followed their course along the esophagus, some going through the esophageal hiatus, some going laterally in the thorax, so that the distribution of every fiber of the right and left gastric nerves could not be determined with certainty. Hence, in this group were found the nerves with a course and distribution which might cause difficulty for the surgeon who attempted to section the gastric nerves.

The relative position of the right and left trunks of the gastric nerves about the esophagus at the point at which they passed through the esophageal hiatus was determined.

Below the esophageal hiatus the course was remarkably constant. The right gastric nerves, the larger in 54 per cent of the dissections in this study, coursed posteriorly and to the left. About 3 to 5 cm. below the esophageal hiatus the right nerve divided to send numerous small branches to the musculature of the stomach—at least they lost their identity in the wall of the stomach. One or more branches followed along the lesser curvature of the stomach; however, the larger single branch followed along the left gastric artery. Routine dissections were not made beyond the division of the right gastric nerve into its branches, since further consideration of the course and distribution was not within the scope of this study.

The left gastic nerve, on the other hand, had a short course in the abdomen. As it came to lie on the anterior surface of the stomach, it almost immediately divided into numerous small branches which lost their identity in the serosa and musculature of the stomach.

Occasionally, a small intercommunicating branch between the right and left gastric nerves below the diaphragm was seen.

In 92 per cent of the dissections in this study distinct right and left gastric nerves could be identified at the esophageal hiatus. In 8 per cent of the dissections the arrangement of one or both gastric nerves was abnormal and irregular. Identification of such nerves, in the performance of gastic neurectomy, would require the thoracic approach.

Discussion

Dr. John H. Grindlay, Rochester, Minn.: Ever since Pavlov's work on the nervous phase of gastric secretion (at that time, fifty years ago, he did not know there was a chemical phase), the gastric nerves have lured surgeons. The recent and broadspread interest in the vagus nerves is merely a revival of interest, and, as has usually been the case, the impetus for this revival has been given by a surgeon, Dr. Lester Dragstedt.

One difficulty has been, and is, even today, that there is no evidence to show that the immediate and sought-for effect of section of the vagi is permanent. Vanzant once showed that the value for free acid in the stomach in dogs might return to about its former level in six months or more after section of the vagi had been performed. In other words, although no free acid was found in the stomachs of her dogs during the first few months after section of the vagus nerves, she found that the ability to secrete free acid might eventually be restored.

Another difficulty is that it is not known what undesirable effects the procedure may have. There is evidence, both clinical and experimental, that troublesome functional disturbances may develop later.

It is true that Dragstedt's first vagotomy was done three and a half years ago, that Moore and Chapman did their first operation two years ago and that in most of the cases reported by these surgeons so far the patient has been benefited. Yet, because of experimental evidence that any change may be only temporary and because long experience with peptic ulcer makes one reserve judgment in respect to any operation until it has been performed in a large series of cases over a period of many years, surgeons in most medical centers, including the Mayo Clinic, are performing gastric neurectomy only in selected cases of peptic ulcer. It is believed that the final report on this operation is not due for some years and that all reports made now and for some years to come should be considered interim reports.

Patients selected for this operation at the clinic are of two general types. The first type of patient is one in whom a new ulcer has developed and who has not had relief of pain from ulcer after an adequate gastric resection. It seems justifiable to offer these patients the comparatively simple operation of gastric neurectomy on the chance that they might obtain relief.

The second group of patients consists of those with chronic, nonobstructing duodenal ulcer, in whom the nervous factor seems to overshadow other factors and for whom surgeons at the clinic believe the operation occasionally may be justified. Some of these patients are young, they have high gastric acidity with active ulcers which respond unsatisfactorily to medical treatment and they conform in a behavior pattern that suggests a prolonged and excessive nervous phase of gastric secretion.

Dr. Bradley and his colleagues have done an excellent and long-needed piece of research. There can be no dispute about their anatomic findings, as there is about clinical and experimental work in this field. If an absolutely complete division of the vagus nerves to

the stomach is necessary to effect a cure of ulcer, their work will be a great help to the surgeon. Until we have had more experience the emphasis should be, certainly, on the completeness of the operation. In the light of this work it will also be appreciated, that when, for some reason, the infradiaphragmatic approach is used, there is an approximately 8 per cent chance that the operation will be incomplete. How important this observation will be eventually, we do not, of course, know.

I should like to take a few more minutes to discuss some of the recent experimental work on this problem. Baranofsky, Friesen and their co-workers, in Wangensteen's laboratory, have reported recently that section of the vagi failed to protect animals from peptic ulcer produced by chronic histamine stimulation. Bollman and I have work in progress in which we are trying to find out whether section of the vagus nerves protects dogs from ulcer produced by the Mann-Williamson operation.* Some years ago Beaver and Mann reported that in one of their small group of three dogs whose vagi had been cut, an ulcer failed to develop after the Mann-Williamson operation. It is this one dog which has been the cause of recent dispute. I am sorry our new experiments are not yet complete.

Bollman and I have just completed a study of the effect of section of the vagi on peptic ulcer produced in dogs by cinchophen. Our dogs were given 2 gm. of cinchophen daily for six days of the week. Peptic ulcers developed about two weeks after this regimen had been started. Most of the dogs died from hemorrhage or perforation. Eleven dogs were used as controls; that is, their vagi were left intact. The vagi were cut in four dogs after an ulcer had developed. Twelve dogs had had their vagi cut at times which varied from three weeks to seven and a half months before the cinchophen regimen was started. Briefly, we found that section of the vagi did not cause the ulcer to heal in the four dogs which already had an ulcer, nor did it prevent the occurrence of an ulcer in dogs whose vagi had previously been cut. I should say at this point that we did almost as radical an operation as that of Moore and Chapman. We excised those portions of the vagi, including their esophageal branches, which extend from a point just below the roots of the lungs to the diaphragm. We were able to verify the completeness of the operation at necropsy.

Perhaps we should expect negative results from such a study. Cinchophen produces an ulcer probably because it stimulates gastric secretion directly, rather than because it stimulates the vagi. It is true also that peptic ulcer as it occurs in man is not a disease of dogs and peptic ulcer which is caused by cinchophen is not a disease with which we are concerned in man.

Nevertheless, one result of the study deserves mention. The dogs in which the vagi had been cut before they were started on the cinchophen regimen lived considerably longer than did the control dogs. The former lived almost twice as long as the latter, they lost less weight, even over the longer survival period, and their ulcers at death looked to be more chronic. The only explanation we can give is that the dogs in which vagotomy had been performed were not affected by the symptoms of ulcer and, consequently, ate better than did the controls, they lost less weight and they were in better condition to survive hemorrhage or a small, early perforation. I think this is of interest because it has been widely reported that patients who, before operation, have had continuous and intractable pain after operation awake from anesthesia completely relieved of pain.

In reference to the paper by Dr. Bradley, I should like to speculate as to whether an absolutely complete section of the vagi and all their visible branches is of importance. Certainly, results have yet to be proved to be related to the completeness of the operation. Perhaps it is necessary to interrupt only the main nerve or certain fibers in the main nerve. In our study of cinchophen-induced ulcer, two dogs which were among those with the longest survival periods were proved at necropsy to have an intact branch of one vagus nerve. One of these dogs gained weight, although he had a large ulcer which had perforated and then had become sealed off; he did not die but was killed after he had been receiving cinchophen for almost four months, which was more than twice as long as any of the control dogs had received the drug.

*The results of this study were inconclusive.

CO-OPERATION BETWEEN THE PHYSICIAN AND THE CANCER SOCIETY

(Continued from Page 252)

for treatment, and the development of new and improved techniques.

It is very likely that further progress will be achieved by advances in medical and surgical treatment and through discoveries in scientific research, provided such research is supported in the future. But even in the present state of knowledge and medical practice, many thousands of lives could be saved annually through earlier diagnosis and treatment. Cancer control is a major challenge not only to the medical profession but to the lay public as well. The final solution, if one is to be found, will be obtained only by co-operative and co-ordinated teamwork between lay leaders, as represented by the American Cancer Society, and leaders in medicine and the allied sciences—all of them working together against one of the most stubborn diseases of mankind.

RECENT ADVANCES IN THE TREATMENT OF CARDIOVASCULAR DISEASES

C. NAUMANN McCLOUD, JR., M.D.

Saint Paul, Minnesota

IN this discussion of recent advances in the treatment of cardiovascular diseases, I will present four different phases of the field which seem to me to be worthy of special emphasis. I will not describe one of the most important advancements, the surgical treatment of congenital cardiovascular defects, because that is a special topic in itself.

First, I wish to discuss the use of penicillin in the treatment of subacute bacterial endocarditis. This disease, as is well known, formerly had a mortality rate of practically 100 per cent.[15] With the advent of the sulfonamides, used in conjunction with heparin or fever therapy, a few cures occurred. Penicillin has completely changed the prognosis in this disease. Penicillin will sterilize the blood stream and heart valves in the great majority of cases, and the small percentage of patients who die do so not because of the septicemia, as formerly, but because of congestive failure, embolic phenomena, or uremia.[2]

The important questions in treating these patients are: how much penicillin should be given per day, and for what length of time? I think we do not have the final answer to these questions. As experience has been gained, the tendency has been to raise the daily dose and give it over a longer time. A daily dose of one-half million units, given for a period of at least twenty-eight days,[2,16] would be regarded now as adequate treatment, provided the organism causing the infection was not highly resistant to penicillin.

It should be emphasized that relapses may occur, and if they do, hope should not be abandoned because such patients will usually respond to larger doses given over a longer period.[3] Relapses, when they occur, almost always do so within thirty days after cessation of treatment.

The proper route of administration of the penicillin is the subject of much controversy. Intramuscular injection every three hours is the simplest method and has given very satisfactory results.[1,2,16] There is no advantage in giving anticoagulants with the penicillin.[3,12]

Next, I wish to discuss the use of the anticoagulants, heparin and dicumarol, in the treatment of acute coronary thrombosis. Parker and Barker[10] have recently published the results of treating fifty such patients with anticoagulants. Only two members of this group developed vascular complications. This is only 4 per cent, which is in contrast to the 37 per cent with vascular complications reported by Nay and Barnes[8] in 1945 in a series of 100 cases of coronary thrombosis not treated by anticoagulants. Three previous authors[9,11,18] have also reported favorable results in the treatment of coronary thrombosis by anticoagulants. The American Heart Association is establishing a program to evaluate this therapy further by means of well-controlled studies in larger centers.

There are definite contraindications to the use of heparin and dicumarol. They should not be used unless a reliable laboratory is available for determining daily prothrombin times. They should not be used in the presence of an ulcer or a bleeding lesion, or in the presence of hepatic or renal insufficiency.

Heparin may be used for the first forty-eight hours until the dicumarol has had time to lower the prothrombin time. Then the patient is maintained on dicumarol. With dicumarol, the prothrombin time should be kept between 10 and 30 per cent of normal. It is well to continue the dicumarol for at least three weeks, as the great majority of vascular complications will occur in this interval. It should be remembered that if the prothrombin time drops too low, or if bleeding occurs, the action of the dicumarol may be counteracted by administering intravenously 60 mg. of vitamin K in the form of menadione bi-sulfite.

Next, I wish to discuss the use of digitoxin, a purified digitalis glycoside, in the treatment of congestive heart failure. While this is not a new product, I think the ease and minimal toxic effects with which a patient can be digitalized are not universally appreciated and are deserving of comment. Harry Gold and his co-workers[4,5] are chiefly responsible for demonstrating the usefulness of this drug.

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1947.

Digitoxin is almost 100 per cent absorbed from the gastrointestinal tract; therefore, the oral digitalizing dose is the same as the intravenous digitalizing dose, and there is no advantage in giving it intravenously. Digitalization is accomplished in the average patient by giving 1.2 mg. of digitoxin orally in one dose. The full effect takes place in four to ten hours. The maintenance dose is .1 to .2 mg. daily. The toxic effects of the single dose are minimal, only one patient in fifty being affected by nausea as a result of local action in the stomach, and only one in fifty affected by nausea as a result of systemic action. An occasional patient may not be fully digitalized by the single dose of 1.2 mg. In this case full digitalization can be accomplished by giving an additional .2 or .4 mg. of the drug.

It should be emphasized that the digitalizing dose should not be given if the patient has received digitalis of any kind in the previous two or three weeks.

Finally, I wish to consider briefly a method of therapy that is not new, but the significance of which has only recently come to be appreciated. I am referring to the treatment of edema by the strict reduction of sodium intake. Schroeder[14] in 1941 and Schemm[13] in 1942 were the first in recent times to advocate marked restriction of sodium intake. Wheeler, Bridges and Paul White[17] have recently confirmed the value of this restriction of sodium and have shown that, in congestive heart failure, fluids may be given *ad lib.* if the intake of sodium is markedly restricted. In the diet of White and his co-workers, the intake of sodium in hospitalized patients was reduced to 1.5 gm. of sodium chloride daily. In their ambulatory patients the regimen was less rigid, and emphasis was placed on eliminating salt from the table and from the cooking, and on using salt-free bread and butter. The reduction of the sodium ion is the important factor, chlorides having no effect on edema formation. Thus no sodium bicarbonate may be given and no medicines containing sodium may be used. White treated thirty-five patients by the low sodium regimen. All of these showed cardiac decompensation uncontrolled by ordinary methods. Of these thirty-five, ten showed great improvement, twelve showed some improvement and thirteen showed no improvement at all. Schemm thinks that, in addition to restricting the intake of sodium, it is important to have the diet acid-ash in type. He thinks fluids should not only be given *ad lib.*, but should actually be forced. The value of forcing fluids in all these patients has not been generally accepted, but the value of the low sodium regimen in uncontrollable decompensation is gradually being recognized.

As well as playing a part in the production of edema, there is evidence that sodium plays some role as yet not understood in the production of essential hypertension. Grollman[6] has obtained improvement in five out of six hypertension patients on a rigidly reduced sodium intake diet, and Kempner[7] reports improvement in 62 per cent of hypertensives with his rice, fruit, sugar diet which is very low in sodium. Further investigation of this form of treatment of essential hypertension is needed.

THE RECOGNITION OF SOME CARDIAC EMERGENCIES AND THEIR TREATMENT

WILBURN O. B. NELSON, M.D.
Fergus Falls, Minnesota

THE recognition of cardiac emergencies, their diagnosis and their management are important considerations in medical practice.

When one first sees a patient who is thought to have had a heart attack, one must determine with accuracy and rapidity whether it is cardiac or noncardiac, such as a benign fainting spell, acute pulmonary edema, acute alcoholism, et cetera.

Acute congestive heart failure is one of the most commonly seen conditions demanding emergency treatment.[12]

Left Ventricular Failure

Acute failure of the left ventricle is observed in patients with hypertensive arteriosclerotic heart disease, frequently following cardiac infarction, in the presence of aortic valvular lesions, notably syphilitic in origin.[5] It is also seen in cases of mitral stenosis and sinus rhythm, and may at times develop after exercise or excitement.

The usual symptoms are paroxysmal dyspnea, often occurring at night, usually without cyanosis but with marked pallor; crepitant râles, particularly at the bases of the lungs; profuse perspiration; marked accentuation of pulmonic second sound; and occasionally gallop rhythm. In severe cases frank pulmonary edema develops.

The differentiation between cardiac and bronchial asthma is of great importance in regard to treatment.[5] Morphine, which is used in cardiac asthma, is definitely contraindicated in bronchial asthma.

Once the diagnosis of left ventricular failure is established, one should administer morphine at once in doses from ¼ to ½ gr. Oxygen should be given as soon as possible. If acute pulmonary edema is present, it is well to do a venesection, removing 500 c.c. of blood. Compression of all four extremities with a tourniquet to withhold the venous blood from the right side of the heart is also valuable. Hoskin[8] states that he has used intravenous strophanthin, gr. 1/100, to steady the heart rate, with some success. Digitalis should be given to aid in the acute attack and to help prevent further attacks. The usual warning about digitalis must be given, however: it must be determined whether the patient has been taking digitalis and, if so, in what dosage. It is naturally imperative that the physician be familiar with the uses and abuses of digitalis and the newer digitalis preparations, if he is to treat cardiac patients intelligently. Mercurial diuretics may also be useful.

Right Ventricular Failure

Right ventricular failure is usually found associated with a long-standing circulatory embarrassment, and occurs as a result of some condition that puts an excess strain on the heart. The chief causes are mitral stenosis and chronic pulmonary diseases. At times, acute right ventricular failure may come on suddenly with the usual signs and symptoms of dyspnea, marked fatigue, nausea and vomiting, cyanosis, dilatation of the right border of the heart, venous engorgement, with corresponding increase in venous blood pressure, enlargement and tenderness of the liver, edema of the extremities, and ascites; hydrothorax may be present, as well as anasarca. The pulse is usually rapid and laboring.

Emergency treatment consists of giving morphine at once; and as in all cases where morphine is given, if the patient is sensitive to this drug, one should give pantopon, dilaudid, or demerol. Oxygen should be started as soon as convenient. Strict bed rest should be maintained. Salyrgan or one of the other mercurial diuretics should be given as soon as possible and followed by subsequent doses every second day until the edema is fairly well controlled. Ammonium chloride in doses of 1.5 gm. is of value if given in large enough doses of from 4 to 6 gm. daily. In some cases it is well to give 50 to 100 c.c. of 50 per cent dextrose solution by slow intravenous injection to replenish the lost glycogen of the cardiac muscle. One must also restrict fluid to 1,500 c.c. daily. As in left ventricular failure, the patient should be started on digitalis.

The differential diagnosis between left and right ventricular failure briefly is as follows:

From the Fergus Falls Clinic.

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1947.

Left Ventricular Failure.

1. Early congestion of the pulmonary tree.
2. Marked accentuation of pulmonic second sound.
3. Pallor, cough.
4. Fall in systolic blood pressure.
5. Usually absence of cyanosis.
6. Frequently follows:
   (a) Hypertensive arteriosclerotic heart disease.
   (b) Myocardial infarction.
   (c) Aortic valve lesions.
   (d) Syphilitic aortic regurgitation.

Right Ventricular Failure:

1. Congestion of pulmonary tree later.
2. Early ascites and peripheral edema.
3. Elevation of venous blood pressure.
4. Venous engorgement, especially noticeable around great veins of neck.
5. Enlargement and engorgement of the liver.
6. Cyanosis.
7. Frequently follows:
   (a) Mitral stenosis.
   (b) Chronic pulmonary disease.

Acute Coronary Occlusion

Coronary occlusion is probably diagnosed more often than it occurs. However, when it does occur, it is a definite cardiac emergency and demands heroic, prompt, and correct treatment.

We are all familiar with the symptoms of coronary occlusion. The pain is usually sternal or epigastric in location, may radiate down the arms and rarely to the back. White[17] states that, "There may be slight transmission of pain to the back and shoulders, but rarely is the pain prominent in the back, as it may be with a dissecting aneurysm." Other signs are lowering of the blood pressure, dyspnea, the characteristic gray pallor of the face, the patient showing signs of shock, as evidenced by sweating, coldness or clamminess of the skin, and rapid thready pulse. Leukocytosis, acceleration of the sedimentation rate, and friction rub are later signs.

On even a tentative diagnosis of coronary occlusion, the patient should be put to bed. A useful rule is: "If the patient presents the textbook picture, the diagnosis is easy. If in doubt, be cautious and prove the absence of occlusion before allowing the patient to be up and about."[11]

The pain may be relieved by morphine, pantopon or dilaudid. If morphine is given, it should be given in sufficient doses to relieve the pain, i.e., from gr. ¼ to ½, and may be given in dosages of ¼ gr. intravenously, repeated, in fifteen minutes if necessary. The intravenous method is preferable in a shocked patient because of the slow absorption by the subcutaneous route, and also because of the possibility of cumulative effects from several subcutaneous injections.[18] One must not, however, give opiates sufficiently to depress the respirations below 12 per minute.

Recently other drugs have been used with marked success for the relief of pain, such as demerol[7] and papaverine. In our experience, demerol has not proven as efficient as the opiates. Papaverine is a powerful local dilator of the vessels in spasm. Papaverine may be given either intramuscularly or intravenously in doses of 0.03 to 0.1 gm. If given intravenously, it may be diluted with 50 c.c. of glucose solution and given slowly; and one may give it every three to four hours, depending upon the character of the pain. Atropine in doses of gr. 1/50 to 1/75, given with the first dose of morphine, is helpful in relieving the cardiac irritability.

Herman states that in severe cases it might be necessary to anesthetize the patient by the intravenous injection of barbiturates such as sodium amytal, 0.06 gm. (1 grain) or in larger doses by mouth in very extreme cases.

Oxygen has been found very useful in the alleviation of the pain of coronary occlusion[2,7,12] and is best given through the BLB mask,[9] as the oxygen tent is at times difficult to operate and may make the patient more apprehensive. I do not like the nasal catheter method, as this is also irritating to the patient and causes an undue irritation of the mucous membranes of the nasopharynx. Alcohol is beneficial when the patient is in collapse with the blood pressure low.[9] It has a tendency to promote vasodilatation and to aid digestion. Caffeine sodium benzoate,[12,13,16] coramine, or metrazol intravenously is indicated if circulatory collapse is present.[13]

If dehydration is present, one should give 50 to 100 c.c. of 50 per cent glucose slowly intravenously,[11,12] to increase the blood sugar and also to build up the glycogen reserve.[6]

Dicumarol has been suggested by Wood[18] to prevent intraventricular clot with subsequent embolus formation. However, he further states that enough is not known about the drug to make it routine. Kossove[10] stated that it should be used routinely, and Sherman[16] pointed out that the infrequency of premonitory signs precludes the use of anticoagulants in the prophylaxis of coronary arterial thrombosis. When giving anticoagulant

drugs, a prothrombin time should be done at least every other day, and preferably every day, and the time should be kept below thirty seconds.

The diet should not exceed 1,200 calories and should be bland.

Enemas and cathartics are best not given for the first four days after an acute occlusion, and then it is advisable to administer a glycerine suppository or a small enema. At times, some of these patients have extreme difficulty in using a bed pan, and then it may be for the best advantage to the patient to use a commode[9] with the patient assisted by two nurses or attendants. For abdominal distention, I have found turpentine stupes very efficacious.

Geiger[7] recommends the use of theophylline diethylenediamine in doses of 0.1 to 0.3 gm. three times daily, or in doses of 0.5 gm. in 200 c.c. of physiological salt solution intravenously, given slowly over a one-hour period to relieve pain and improve circulation. Day[4] recommends the use of aminophyllin, 0.25 gm., early in the occlusion. I have used 0.5 gm. in 250 c.c. of 20 per cent glucose solution once to three times daily, given at the rate of 40 drops per minute intravenously, with the view of relieving pain, improving the circulation, building up the glycogen of the cardiac muscle, and somewhat preventing dehydration.

Quinidine is not part of the emergency treatment, but it is well to give it following the emergency period to prevent some of the arrythmias, such as ventricular tachycardia and auricular fibrillation, frequently seen in acute coronary occlusion.

Digitalis should be used in cases where congestive failure exists[14] together with the acute occlusion, but is contraindicated where congestive failure or auricular fibrillation does not exist.[3] It is a safe practice slowly to digitalize patients with acute coronary occlusion, with co-existing congestive heart failure or auricular fibrillation, and at the same time to give small doses of quinidine (3 grains twice to thrice daily). It has been proven in cases of auricular fibrillation complicating acute coronary occlusion, that digitalis should not be given alone but in conjunction with quinidine.[1]

One word of caution should be given about the overenthusiastic use of the cardiogram in acute coronary occlusion. It is my practice not to take an electrocardiogram for the first twenty-four to forty-eight hours, where the diagnosis is established without doubt, for, as Reinfenstein[15] has said, "A patient recovering from coronary thrombosis without an electrocardiogram is better than a dead one with an electrocardiogram."

The subsequent treatment of occlusion of the coronary arteries does not come under acute cardiac emergencies.

Pericardial Effusion

Fluid may accumulate in the pericardial sac either as an inflammatory exudate, as a complication of rheumatic fever, tuberculosis, septic infection of the pericardium (as in pneumonia), or malignancy of the pericardium, or as a transudate as seen in congestive heart failure, renal disease and other disorders showing generalized anasarca. If the fluid accumulates slowly, 500 to 1,000 c.c. may be formed without causing symptoms, but if it forms rapidly, much less fluid may seriously hamper cardiac function.

There are relatively few symptoms and signs in the early stages of pericardial effusion or hydropericardium. As fluid accumulates, however, the patient shows marked dyspnea, cyanosis, distension of the veins in the neck, liver engorgement with pain in the abdomen, fall of blood pressure, and increase in respiratory rate; and pulsus paradoxus might ensue.

When this occurs, it is essential that the patient is given relief, by giving opiates or other pain-alleviating drugs, and by doing a paracentesis, as Marvin states, for two reasons: "To remove fluid (1) because of its quantity or the rapidity of its formation is hampering the heart's action and interfering with the venous return to the auricles, and (2) for the purpose of diagnosis, especially when pus is thought to be present." In cases of rheumatic infection, one usually does not resort to paracentesis of the pericardial sac, because the effusion seldom becomes very large and a spontaneous regression usually occurs.

If the effusion present is purulent, one can insert penicillin solution into the pericardial sac.

Conclusion

There remains a great deal more to be said about cardiac emergencies, as, for example, the arrythmias, but time does not permit. There are but two factors that I should like to emphasize further.

1. Every physician who attempts to diagnose

(Continued on Page 312)

TREATMENT OF CONGESTIVE HEART FAILURE

BEN SOMMERS, M.D.
Saint Paul, Minnesota

WE may divide the treatment of congestive heart failure into three parts without regard for the etiology: treatment of early left, acute left, and chronic right heart failure.

A patient with symptoms of early or mild left heart failure comes to his physician complaining of dyspnea on exertion, orthopnea, and attacks of nocturnal dyspnea. Although generalities in treatment of heart failure are always dangerous, each patient being very much of an individual problem, nevertheless the majority of these patients may be treated on an ambulatory basis without the strict bed rest formerly prescribed. In fact, many may continue at sedentary employment without loss of work if rest periods can be provided. In these cases, therapy consists of full digitalization followed by a maintenance dose sufficient to maintain full digitalization. This procedure is also required in the treatment of the other types of heart failure to be described later. In other words, heart failure is an indication for digitalization, irrespective of etiology and whether auricular fibrillation or regular sinus rhythm is present. Since the patient with early left heart failure does not have to be treated as a cardiac emergency, oral digitalization is the method of choice, and the whole leaf tablet of digitalis folia is still generally satisfactory. The total digitalizing dose may be easily calculated on the basis of one cat unit per ten pounds of body weight, one quarter of this dose being given every eight hours. Undue sensitivity will be noted by careful observation during this period; or if this is impossible, several days may be taken for digitalization, adding one cat unit extra for each day. Thereafter, one cat unit will serve as the average daily maintenance dose, although some patients require as little as one quarter of one cat unit daily and others as much as three. Because of variations in potency of different brands of digitalis folia, one should choose a single reliable brand and learn its potency by clinical trial.

The newer crystalline glucosides of *Digitalis purpurea* and *lanata* are being used more generally, their advantages being greater uniformity, more rapid absorption, and less toxicity. Many cardiologists still prefer the whole leaf tablets when rapid digitalization is not necessary, or for maintenance dosage. Several different brands of digitoxin are now available in 0.1 and 0.2 milligram tablets. The total digitalizing dose lies between 1.2 and 1.6 milligrams, and this may be given at once if rapid digitalization is desired. Maintenance dosage varies usually between 0.1 milligrams and 0.2 milligrams per day. Lanatoside C, a pure glycoside obtained from *Digitalis lanata,* is available under the trade name of Cedilanid, supplied in tablets for oral administration of 0.5 milligrams each and in 2 c.c. and 4 c.c. ampules of 0.4 milligrams and 0.8 milligrams for intravenous use. Ten to twelve tablets orally or 8 c.c. intravenously, are average total digitalizing doses; one or two tablets daily are the usual maintenance requirements.

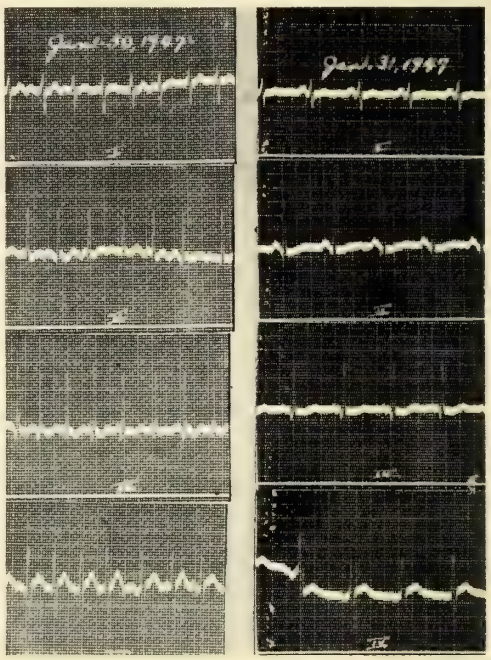

Fig. 1.—*Case 1.* Electrocardiograms on first and second day of hospitalization showing auricular fibrillation and right axis shift on January 30, and return to normal sinus rhythm on January 31. Some digitalis effect is evident.

It is well to re-evaluate the patient's degree of digitalization every six months by adding an extra tablet daily until symptoms of toxicity ap-

Read in part at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1947.

pear, or by discontinuing the drug for two or three weeks and redigitalizing fully at the end of this period.

Strict limitation of fluids or salt will probably not be necessary in a case of early left heart failure, but the patient should be warned that excessive consumption of liquids of any kind may precipitate symptoms of failure.

Case Report

Case 1.—L. S., a forty-year-old insurance salesman whose mitral stenosis was discovered accidentally in 1941, had been well until the onset of mild exertional dyspnea in December, 1946. In the early morning of January 30, 1947, he presented the picture of acute left heart failure, with marked dyspnea, orthopnea, rapid and irregular ventricular rate of 180 to 210, and cyanosis of the lips and fingernails. He coughed continuously, raising blood-tinged frothy sputum and occasional clots of blood. Besides the congestive râles heard bilaterally, a pleural friction rub was heard in the left axilla. The rectal temperature was 101.5° F.

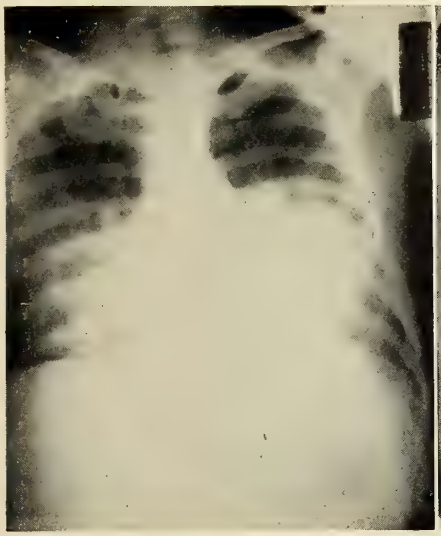

Fig. 2.—*Case 1.* Bedside chest film shortly after admission showing mitral configuration of the heart, pulmonary congestion, and consolidation in left lower lobe due to pulmonary infarction.

Fig. 3.—*Case 2.* Six-foot plate in January, 1945, showing marked cardiac enlargement and infiltration at right base probably due to fluid and old areas of pulmonary infarction.

Should nocturnal dyspnea persist after digitalization, diuretics, particularly the mercurial diuretics, may be given. A weekly injection of 1 or 2 c.c. of salyrgan, salyrgan-theophyllin, or mercupurin will often suffice. Some of these compounds are now available in tablet form for oral administration, and work quite efficiently with few toxic manifestations. Three to six tablets, daily, one or two days per week often work as efficiently as daily administration. The effect of mercurial diuretics may be enhanced by giving 4 grams of ammonium chloride or nitrate on the day before and the day after injection. Whether these salts increase the efficacy of the orally administered mercurial diuretics remains unproven.

Finally, suppositories of aminophyllin may be used at night to control nocturnal dyspnea.

Acute left heart failure may be a real medical emergency, taxing the skill of the physician and requiring prompt treatment. The following case exemplifies the problems involved:

Here, then, was acute left heart failure with rapid auricular fibrillation and pulmonary embolism. Morphine sulfate, gr. 1/6, was given intravenously and the patient was hospitalized and given 100 per cent oxygen by mask. Digitalization was accomplished by the administration of 8 c.c. of Cedilanid, given intravenously in about eight minutes. More morphine was given intravenously, the patient's condition appearing critical, with dyspnea approaching exhaustion. Five hundred c.c. of blood were withdrawn rapidly by venesection. Clinical improvement became definite. Air hunger and cyanosis had almost disappeared, and the ventricular rate was 90 to 95.

From the history it was assumed that auricular fibrillation was of recent onset and had probably initiated both the acute left heart failure and the pulmonary embolism. Quinidine sulfate was therefore given orally, a 3-grain sensitivity dose being followed in one hour by 6 more grains, and this amount was repeated every three hours. Normal sinus rhythm was established after 18 grains of quinidine had been given, and sixteeen

hours after admission the pulse rate was 80 and clinical improvement was striking. A maintenance dose of quinidine sulfate, gr. 3 four times daily, and Cedilanid, two tablets daily, was prescribed. Oxygen was discontinued after thirty-six hours, and convalescence was uneventful. He left the hospital on the fifteenth day (Figs. 1 and 2).

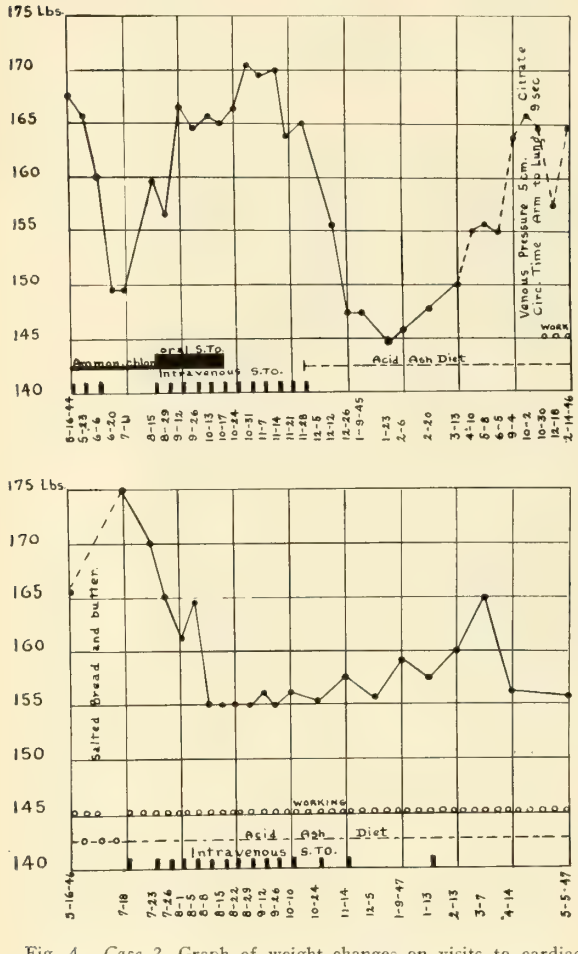

Fig. 4.—*Case 2.* Graph of weight changes on visits to cardiac clinic. Broken line represents weight while patient failed to obtain unsalted bread and butter. S.T.O. abbreviation for Salyrgan-Theophyllin.

In summary, acute left heart failure is a medical emergency often requiring a variety of therapeutic procedures, the most important being morphine, digitalis, oxygen, and in some cases venesection and diuretics.

Chronic right heart failure is a problem in edema control. If edema persists after digitalization and adequate rest, sodium intake should be sharply curtailed. F. R. Schemm believes that the diet should have an acid or a neutral ash, that dilute hydrochloric acid should be supplemented to insure proper acidity in order to liberate sodium in the intercellular spaces, and that a high fluid intake is important to promote diuresis and excretion of the liberated sodium. This method is quite satisfactory in patients with chronic dropsy provided the diet is strictly followed. In less severe cases, occasional use of the mercurial diuretics will suffice. The following case illustrates management of severe dropsy with both methods.

Case Report

Case 2.—F.B., a white man, sixty-two years old, first entered Ancker Hospital in 1944 with hypertensive heart disease, coronary sclerosis, auricular fibrillation, and right heart failure. Bilateral hydrothorax, ascites, and leg, ankle and sacral edema were present. Marked stasis dermatitis of the shins was striking in appearance, thick white scales overlying a mahogany-colored markedly edematous leg. Digitalization, prolonged bed rest, and large doses of both ammonium nitrate (grams 4 to 6 daily) and mercupurin (2 c.c. once or twice weekly) produced definite clinical improvement, but anasarca remained a problem.

Weekly or bi-weekly visits to the out-patient cardiac clinic for salyrgan-theophyllin intravenous injections followed hospitalization, the patient's weight and degree of edema showing the fluctuations one sees in these severe cases of dropsy with variations in their fluid intake and salt intake. His fluid intake at this time was supposed to be limited to between 800 and 1,000 c.c., but he frequently complained of thirst and undoubtedly greatly exceeded his quota on many occasions. (Schemm uses as one argument in favor of his high fluid intake for cardiac edema this common complaint of thirst in those treated with a low fluid intake). He had been warned to restrict his salt, and a "low salt cardiac diet" sheet was provided, but no issue had been made of the necessity of obtaining salt-free bread, butter, and salt-free vegetables.

On November 28, 1945, all diuretics were discontinued and the patient was given a strict full neutral ash diet after the manner of Schemm. A high fluid intake was obtained by the consumption of a glass of water hourly from 7 a.m. to 7 p.m., three drops of dilute hydrochloric acid being added to each glass. Digitalis was continued in a maintenance dose.

Figure 4 illustrates the patient's weight variations before and after the Schemm regime was initiated. The initial 20-pound weight loss was followed by an increase of 5 pounds as his appetite improved. Vigor and strength increased so that he was able to return to work, shoveling paper into a furnace in a paper box factory.

Between the middle of February and July, 1946, he was seen only once in clinic, and it was not until the latter month, with return of his edema and marked increase in his weight, that questioning revealed the cause. He had failed to obtain unsalted butter and bread. Resumption of the strict diet plus the help of a few injections of a mercurial diuretic (these were

GENESIS OF RHEUMATIC FEVER

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

THE definition of genesis according to Webster's New International Dictionary is "natural development into being." The purpose of this presentation, then, is to crystallize the available knowledge on the factors which precipitate acute rheumatic fever, and to discuss briefly the nature of the tissue reactions which take place in this disease.

Precipitating Factors

Role of Infection.—For many years, acute rheumatic fever has been considered by many competent authorities to be an infectious disease. In this country, the outstanding observations of Coburn[2] were among the first to center interest on the hemolytic streptococcus as one of the responsible agents, at least, for rheumatic fever. The concept that the hemolytic streptococcus is related in some undefined manner to rheumatic fever is now accepted by many investigators in this field. It is of interest that in 1927 Dr. Homer Swift of the Rockefeller Institute, who has devoted many years to the study of this disease, wrote in the first edition of Cecil's *Textbook of Medicine* as follows: "Rheumatic fever is a disease of undetermined etiology characterized by fever and a toxic state. . . ." Twenty years later, in 1947, Dr. Swift has included the section on "Rheumatic Fever" under streptococcic diseases in Cecil's seventh edition, and writes: "Rheumatic fever is a disease, infectious in nature, closely associated with invasion of the body by Group A hemolytic streptococci." Without detailing all the evidence in favor of the hypothesis that the hemolytic streptococcus is implicated in the genesis of rheumatic fever, the following may be stated.

1. Upper respiratory infections due to Group A hemolytic streptococci, such as nasopharyngitis, tonsillitis and scarlet fever, are frequently closely followed by rheumatic fever. In fact, epidemics of rheumatic fever have been associated with large numbers of cases of streptococcic respiratory disease.

2. Recurrent attacks of rheumatic fever are often preceded by streptococcic respiratory infections.

3. Patients with active rheumatic fever reflect certain immune responses characteristic of invasion of the tissues by hemolytic streptococci, such as an increased titer in the serum of antistreptolysin, antifibrinolysin and anti-M precipitins.

4. Although the sulfonamides do not alter the course of rheumatic fever, carefully controlled studies indicate that the prophylactic use of these compounds will prevent the invasion of tissues by hemolytic streptococci and thereby reduce the incidence of recurrent attacks of rheumatic fever.

The precise role of hemolytic streptococci in the genesis of rheumatic fever is not clearly understood, but the mechanism has been compared to the sequence of events which take place in human beings following the parenteral administration of horse serum. In other words, rheumatic fever is a manifestation of tissue hypersensitivity to the hemolytic streptococcus. Clinically, this relationship may be delineated by characterizing three phases of streptococcic diseases as follows:

Phase I	Phase II	Phase III
Suppurative and Toxic Phase Nasopharyngitis, tonsillitis, scarlet fever, puerperal sepsis, et cetera	*Latent Phase*	*Nonsuppurative Phase* Acute rheumatic fever

Phase I represents the initial invasion of the tissues by Group A hemolytic streptococci. This phase is characterized by suppuration, but the disease may be so mild that it may be completely overlooked. Although suppurative complications are largely prevented with available chemotherapeutic agents, the early use of the sulfonamides or antibiotics, even in the mildest cases, will not prevent the subsequent development of rheumatic fever. Successful chemoprophylaxis in rheumatic fever means the prevention of the invasion of tissues by hemolytic streptococci. Present-day chemotherapy limits the more severe manifestations of Phase I to a few days. The generally accepted opinion is that Phase II is a latent or asymptomatic period lasting from two to six weeks before the onset of Phase III or acute rheumatic fever. However, recent evidence would indicate that the

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1947.

period immediately following Phase I may be marked by extensive tissue reactions which are reflected in failure of the patient to regain his normal sense of well-being, low-grade fever, tachycardia, leukocytosis, accelerated erythrocyte sedimentation rate, and abnormal electrocardiographic findings.[7] These features indicate the presence of rheumatic fever, and may be so insidious that an undetected valvulitis may ensue. This may explain in part why it is so difficult to elicit a history of a frank attack of rheumatic fever in individuals with inactive rheumatic valvulitis. Nevertheless, Phase III, which is considered to be the stage of late nonsuppurative manifestations of hemolytic streptococcic infections, particularly upper respiratory diseases, is frequently ushered in with the explosive onset of migratory polyarthritis, fever, tachycardia, myocarditis, pericarditis, and valvulitis. Several possibilities exist as to the ultimate outcome of the patient having an initial attack of rheumatic fever. According to Keefer,[4] 2 to 5 per cent of all patients with acute rheumatic fever die within the first year, while the incidence is between 15 to 20 per cent in those individuals with evidence of acute carditis. On the other hand, it is estimated that, following an initial attack, between 15 and 30 per cent of the patients will recover completely without any residual cardiac damage. Unfortunately, in patients who recover completely or in those who recover with a residual valvular damage, there lurks the constant threat of recurrent attacks, particularly in children under fifteen years of age. And finally, bacterial endocarditis may be superimposed upon a healed but scarred rheumatic valve.

In summary, then, the writer is of the opinion that Group A hemolytic streptococci are related in some way to the onset of acute rheumatic fever. At the present time, the most logical concept of this relationship appears to be a state of hypersensitivity of the tissues to the streptococcus. The possibility that other microbes may initiate the disease is not denied. In fact, following cardiac damage by an initial attack of rheumatic fever, there may be several "trigger agents" which may be responsible for recurrent attacks of the disease. These may include microbes other than the hemolytic streptococcus.

Host Factors.—Although there is accumulating evidence that rheumatic fever is an infectious disease, there are other factors which enter into the genesis of the disease. One of these additional factors is the susceptibility of the host. Rheumatic fever has its greatest attack rate in children between the ages of three and fourteen years, with the highest frequency for initial attacks at about six or seven years. It is unusual for rheumatic fever to occur in infants. On the other hand, the disease is not at all uncommon in adults. The writer has observed an initial and fatal attack of rheumaic fever in a man over seventy years of age.

Another interesting feature about rheumatic fever is the existence of a hereditary predisposition for rheumatic fever. Several familial studies have indicated such a relationship.[6]

Environmental Factors.—Rheumatic fever has long been considered a disease of the temperate regions, occurring most frequently in cold and wet climates. However, it should be pointed out that the disease is quite prevalent in areas having a mild and dry climate such as Colorado and Utah. A considerable number of cases occurred in the military personnel during the past war in these areas, and the occurrence of the disease was associated with epidemics of upper respiratory disease due to the hemolytic streptococcus. Rheumatic fever is more prevalent in urban areas than in rural areas, which may be related to crowding and more intimate exposure to streptococcic disease. It is frequently stated that economic factors also enter into the genesis of the disease, the attack rate being greater in the poorer classes than in the rich. Malnutrition has also been considered a factor. Here, again, it is essential to bear in mind that poverty and malnutrition are associated with crowding, and that the element of exposure may be of more fundamental significance.

Tissue Reactions

The nature of rheumatic fever may be defined further by briefly outlining the tissue reactions that occur. Basically, rheumatic fever is a disease of mesenchymal tissues, namely, connective tissue and blood vessels. The initial lesion involves the collagen, causing focal areas of swelling, separation of the fibers by edema, swelling of the fibers, and then degeneration of the fibers. Associated with this tissue reaction, and much more prominent clinically, are exudative phenomena involving the joints, pleurae and pericardi-

um. Following these early tissue changes, there is the appearance of a characteristic type of proliferative reaction. This latter reaction is best exemplified by the rheumatic granuloma or Aschoff nodule, and is most conspicuous in the myocardium. Similar but less well defined proliferative lesions are found in the subcutaneous tissue, larger blood vessels, endocardium and heart valves. Clawson[1] has maintained that the Aschoff nodule is not specific for rheumatic fever. The ultimate outcome of this proliferative type of lesion, according to Swift,[11] is the replacement of granuloma cells by fibroblasts, resulting in formation of scar tissue, and the appearance of more collagen than existed originally. He also makes the significant statement that whereas salicylates cause a reduction in the inflammatory or exudative reaction, these drugs do not alter the course of the proliferative type of reaction. Thus, with the administration of salicylates, joint pain and the accompanying effusions abate, but subcutaneous nodules continue to make their appearance.

One of the difficulties that has persistently blocked a better understanding of the genesis of the lesions in rheumatic fever has been the failure to reproduce the disease experimentally in animals. Recently, Rich and Gregory[8,9] reawakened interest in this subject when they produced an anaphylactic type of tissue response in rabbits with horse serum. Histological studies of the myocardium revealed lesions closely resembling those of rheumatic carditis. In summarizing his experimental data, Rich[10] concluded that rheumatic fever represents focal hypersensitive reactions of the anaphylactic type to an antigen or antigens to which the body has been sensitized. While present evidence implicates the hemolytic streptococcus as the most common sensitizing antigen, it is not unlikely that antigens other than the hemolytic streptococcus may be responsible for some cases of rheumatic fever. The observations of Rich and Gregory have been confirmed by Fox and Jones,[3] and Kyser, McCarter and Stengle[5] have also produced a similar type of myocarditis in rabbits with horse serum and have made the additional significant observation that antihistamine drugs such as benadryl will impede the development of the lesions. It is becoming more and more clear that further studies on experimental rheumatic fever should include the utilization of several species of animals as well as different types of antigens.

Summary and Conclusions

This brief review indicates that there are many complicating factors that enter into the elucidation of the problem of the genesis of rheumatic fever. Although there is more than suggestive evidence that the hemolytic streptococcus is responsible for some cases of rheumatic fever, the precise mechanism whereby this species of bacteria provokes the disease is not clearly understood. The most logical working hypothesis at the present time is that in some cases, at least, there exists a hypersensitivity of the tissues to the hemolytic streptococcus. In addition, there are certain ill-defined host factors such as an inherited susceptibility of the tissues to this type of sensitivity. Further investigations are highly desirable on the relationship of the susceptible host to environmental factors such as exposure to infection and the response of the tissues.

INCIDENCE OF PULMONARY EMBOLISM AFTER VENOUS SCLEROSING THERAPY

FREDERICK L. SMITH, M.D., and MARCELLUS A. JOHNSON, III, M.D.
Rochester, Minnesota

PULMONARY embolism through the ages has been one of the most feared catastrophes in the treatment of patients whether medical or surgical. Robertson, former head of the Section on Pathologic Anatomy of the Mayo Clinic, aptly stated in regard to postoperative embolism: "Suddenly, almost always, out of a clear sky there is strange restlessness, rapidly ensuing shock with substernal distress, air hunger, collapse and death in a few minutes. The horror of the patient's relatives is echoed by the poignant distress and shock of the attending surgeon, colleagues and nurses" and may we add, to the friends in the community in which the patient resided.

In a statistical review of the records of postmortem examinations at the Mayo Clinic over a ten-year period, 1917-1926, Henderson found 313 cases of pulmonary embolism, 267 being surgical cases and forty-six nonsurgical. In 223 (83.5 per cent) of the cases the emboli were the primary cause of death. The average age of the patients was 53.2 years. Nineteen of the forty-six nonsurgical cases were cases of cardiovascular disease. The source of emboli was most commonly in the iliac, femoral or pelvic veins, prostatic plexus or vena cava in the order named. We believe that the incidence of fatal pulmonary embolism has decreased in recent years. Other studies have revealed this decrease. Some of the reasons for this decrease are as follows:

Anticoagulants have been introduced to forestall an acute or remote possibility of pulmonary embolism. Their proper use is well described by Allen, Barker and Hines. The value of anticoagulant therapy is clearly indicated by the report of Barker and his associates on 1,000 specially selected surgical patients who were given dicumarol in the immediate postoperative period. In the entire series only one death occurred from pulmonary embolism. This extremely low incidence of fatal pulmonary embolism is remarkable because 379 patients had demonstrated a thromobotic tendency at some time before operation and 438 had been subjected to abdominal hysterectomy. The statistical risk of thrombosis and embolism in abdominal hysterectomy is known to be high. One of us (F.L.S.), in an unpublished study on postoperative complication made in 1919, also observed this high incidence following abdominal hysterectomy.

The surgical interruption of the femoral vein was recommended for pulmonary embolism by Homans in 1934 and from 1941 on, in the medical service of the Massachusetts General Hospital, ligation became the treatment of choice but it usually was performed only on the affected side.[5] In 1943, bilateral interruption regardless of noninvolvement of the other extremity became the routine treatment of pulmonary embolism on that service. By the last procedure Carlotti and his associates at the Massachusetts General Hospital reduced the mortality rate from pulmonary emboli in the medical cases in the years 1941 to 1945 to 28.3 per cent as compared to 50.7 per cent in medical cases in which this procedure was not carried out after a nonfatal episode of pulmonary embolism.

In cases in which sclerosing treatment of varicose veins is planned at the Mayo Clinic, special care is taken in examining the extremities for evidence of vascular disease and in eliciting a history of any previous episodes which could be interpreted as being due to vascular disease of the lower extremities. Often localized atrophy, with brawny induration and discoloration, or slight edema of the leg suggesting some previous episode of thrombophlebitis is found. At the time this episode occurred, it often was not considered of any special significance by the patient or physician, if consulted, but was passed off as extraneous. Sometimes a patient who has had previous sclerosing treatment of a vein may volunteer the information or respond to a question to the effect that a few days following this treatment he had awakened at night "with a touch of pleurisy," had had difficulty in breathing or

From the Section on Postoperative Care (Smith) and the Mayo Foundation (Johnson—Fellow in Surgery).

Read at the meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 8, 1947.

possibly had had rusty expectoration for which he took some aspirin, applied a mustard poultice to the affected side or remained in bed for a few days. In all probability an embolic episode was the source of the trouble. Doubtless many more respiratory episodes of this type occur after sclerosing treatment than are reported. This failure is due to lack of understanding of the true condition. The embolic accident when it does occur may be due directly to sclerosing treatment, or possibly its occurrence is a coincidence and previous episodes have followed an ancient thrombophlebitis.

Special care is taken in cases in which previous episodes or some indication of vascular disease is obtained. In our experience in sclerosing treatment of varicose veins at the Mayo Clinic we have found that the massive type of embolus is seldom encountered in such cases but rather small emboli occur which involve the lungs in varying degrees. A shotty appearance in the base of one or both lungs may be evident in the roentgenogram.

From 1927 through June 30, 1947, 11,700 patients have been treated for varicose veins at the Mayo Clinic and only seventeen of these patients (0.14 per cent) have had pulmonary emboli. Sixteen had nonfatal emboli and recovered without subsequent sequelae, and one had a fatal embolus. Prior to March, 1937, treatment in our series consisted mainly of injections. After 1937 the combined ligation and injection technique was used. This technique consists of injection of a sclerosing solution into the distal segment at the time of ligation of the great or small saphenous vein. Our yearly reports reveal that from 80 to 88 per cent of all patients were treated by the above procedure and the remainder received injections only. In 93 per cent of the cases in which operation was performed, the great saphenous vein and its tributaries were ligated and in 7 per cent the small saphenous vein was ligated in the popliteal space.

We have attempted to determine whether the seventeen patients who had pulmonary emboli had any characteristics which distinguished them from the patients whose course was uncomplicated. All seventeen were referred for venous therapy after complete examination. There were nine men and eight women. Their average age was fifty years. Three had mild hypertensive diseases, one had duodenal ulcer, one localized lupus erythematosus and one slight pneumoconiosis. One gave a history of deep thrombosis of the femoral vein ten years previous to coming to the clinic but complete involution had occurred before examination in the section on venous therapy. Varicose veins had been present for an average of twenty-seven years in the seventeen cases and the average length of time during which discomfort had been manifest was six years. Four patients had varices on one lower extremity only and thirteen had them on both lower extremities. Six had varicose ulcers. In six cases the embolic episode developed prior to 1937, whereas after 1937 when ligations were instituted, eleven occurred. In these eleven cases combined ligation and injection was employed.

The sclerosing solution used for the most part in our entire series was a 5 per cent solution of sodium morrhuate although a 10 per cent solution was used when a more concentrated solution was required. Quinine and urethane (Génévrier's solution), a solution of 50 per cent glucose and 25 per cent salt, 30 and 40 per cent solutions of sodium salicylates and 20 per cent solution of salt were all used early in the work but sodium morrhuate proved to be the solution of choice.

Always to identify patients during the treatment period who are likely to develop an embolic condition is practically impossible as all exhibit swelling and tenderness with local increase of heat resulting from the chemical endophlebitis. Occasionally chills and fever with moderate to high leukocyte count will be observed; this episode lasts for twenty-four hours or so and then the leukocytosis recedes. The local tenderness and swelling may last for some days. Their duration depends on the size of the vein treated. Our earliest embolic episode was four days and our latest sixteen days after beginning of treatment. In fifteen cases roentgenograms showed sufficient evidence to warrant a diagnosis of embolism with ensuing infarction.

Just what initiates the development of a thrombus is a matter of conjecture and in the literature reviewed various explanations were advanced.[2] Investigators are generally agreed that the basic principle on which they have been working is the prevention of formation of thrombi in the deep veins of the lower extremities. Enough information has been gathered to attribute the formation of a thrombus in many cases to operative

procedures. Allen and Linton reported that debilitated persons with restricted mobility of the lower extremities are likely to have thrombosis. Yet Munro in discussion of Albright's paper, stated that in the army general hospitals in England pulmonary embolism rarely occurred in 250 cases in one series and in 500 in another in which patients paralyzed because of injury to the spinal cord were confined to bed and their legs were immobile for months. Thrombosis is prone to develop in association with trauma and infections. All investigators have observed the increased incidence of thrombosis in patients more than forty years of age.

It is difficult to determine why an embolus develops during active sclerosing treatment. Chemical endophlebitis should anchor the thrombus at the site of the injection. Tributary communicating veins may be a factor for phlebothrombosis may develop in them although the walls of the veins may not be affected, and some muscle contraction may express the soft jelly-like clot into the deep circulation. Necropsy has revealed that clots had formed during life and propagated rapidly toward and into the large veins with no evidence of injury to the vein walls but simply with stasis or stagnation of circulating blood.

Inasmuch as thrombophlebitis of the lower extremities is the main factor in surgical procedures regardless of the site of the operation, patients who have undergone injection treatment and operation, especially those confined to bed, should have leg and foot exercises at frequent intervals and, when physical condition permits, actual walking is beneficial.

Before the days of anticoagulants at the clinic we hospitalized at once patients who had pulmonary emboli after sclerosing treatment, placed them in the Fowler position and immobilized the chest as much as possible with binders and by the hypodermic use of morphine sulfate every four hours until the respiratory rhythm was reduced to 10 or 12 per minute. Enough sedation was given to keep the patient in a semicomatose state in an oxygen tent containing a mixture of 50 per cent oxygen. The oxygen compensated for the low volume intake and also more or less prevented pulmonary abscess or bronchiectasis if these did not previously exist. We found that if the patients with a severe involvement did not die in twenty-four hours, they recovered.

It is now our practice to hospitalize any patient who is suspected of threatening venous clotting, as a prophylactic measure and to begin anticoagulant therapy immediately. If the consultants on the vascular service advise operation because of likelihood of a thrombotic migration from thrombophlebitic involvement in the extremity, the region of the deep veins of the extremity is explored and ligation is performed.

Summary

In the period 1927 through June 30, 1947, 11,700 patients were given sclerosing treatment for varicose veins at the Mayo Clinic. In seventeen of these pulmonary embolism developed, an incidence of about 1.4 per thousand. There was only one death in the series from pulmonary embolism. In our experience anticoagulant therapy has proved adequate when venous clotting appears likely or nonfatal pulmonary embolism occurs and occasionally operation is resorted to in addition. A thorough preliminary history and examination are essential in cases in which sclerosing treatment is planned.

Case Reports

EPISTAXIS

ORIEN B. PATCH, M.D.
Duluth, Minnesota

EPISTAXIS is hemorrhage from the nasal cavity. It may vary in quantity from a mere trickle or trace to a free flow of blood so severe that syncope will follow and serious anemia be produced. Death may occur from prolonged and repeated nasal hemorrhages.

While epistaxis is not near and dear to the hearts of most otolaryngologists, all of us are faced sooner or later with the problem of nasal hemorrhage, whether it be mild and prolonged or severe and profuse.

I wish to present case which apparently had a perfectly innocent onset and developed into something quite the opposite as far as etiology and end results were concerned.

Case Report

A patient, Mrs. L. D., aged fifty-eight, was seen on the evening of December 26, 1946, at St. Mary's Hospital, at the request of her family doctor. She had been bleeding from her left nostril for twenty-six hours.

The examination on admission was confined to the head, and particularly to the nasal cavities, because of the critical condition of the patient. The only positive finding was a simple erosion about 6 mm. in diameter, round, and not penetrating as deep as the cartilage in Kiesselbach's area on the left.

The nasal mucosa was shrunk with 0.5 per cent neosynephrine and anesthetized with 1 per cent pontocaine spray; cotton was placed in the posterior choanae, and all clots were removed with a nasal suction tip. Then the area was cauterized with a silver nitrate stick. The lesion still oozed.

Next, the mucosa of the area was elevated by injecting 1 per cent procaine containing 3 minims of adrenalin to the ounce. After ten minutes the area bled again.

Finally, I used trichloracetic acid, neutralized it with bicarbonate of soda, and applied Gelfoam with sterile trombin, and the bleeding ceased.

Six hours later she oozed again, and 10 c.c.'s of the patient's own blood plus 1 ampule of Hykinone were injected intramuscularly. She did not bleed until the next day.

The following day the relatives were interviewed, and it was revealed that on January 26, 1946, she had had a left mastectomy. The pathological diagnosis of the removed breast showed carcinoma simplex with seven lymph nodes involved.

On the same day as the interview with the relatives and the general examination of the patient, she bled again from the right side of her nose and from an area similar to the one previously described on the left side.

This time electrocautery was used at once, and I had visions of perforation of the septum, since the two cauterized areas were directly opposite each other. Simultaneously, she was again given Hykinone, one ampule. This was followed immediately by two blood transfusions. Her blood counts next day were as follows: red blood cells 2,710,000, white blood cells 4,300, with a differential count showing polymorphonuclears 65 per cent, lymphocytes 25 per cent, monocytes 3 per cent, and new "stab" forms 7 per cent.

X-rays of the lumbar spine and the pelvis on December 27 showed no metastatic malignancy. An x-ray of the sinuses showed no bony destruction. The blood cultures were negative. The chest plate was normal, except for left ventricular hypertrophy. The patient had a few bouts of slight oozing which gradually ceased. Nasopharyngoscopic examination failed to show any abnormality in the epipharyngeal vault, but there was considerable vascular congestion of the area.

She was given five deep x-ray treatments to her nose between January 13 and 18.

It was during this time that a small firm mass, about 1 cm., in diameter, was noticed above her left eye. It was almost rock-like in consistency. Small petechiae appeared in her soft palate, and a few hemorrhages were present in the fundus of the left eye. At the same time she showed some hemorrhage behind her left ear drum, accompanied by a mild conduction deafness with the Weber to the left.

Her blood picture on January 20, following her third transfusion, was alarming: red blood cells 880,000, white blood cells 9,100, hemoglobin 21 per cent, platelets 120,000, bleeding time 23 minutes and 30 seconds (checked), and clotting time 3 minutes and 30 seconds.

She was put on (1) cevitamic acid, 100 mg., t.i.d., (2) Cenolate, 200 mg., intramuscularly, q.d., (3) Demerol, 100 mg., q.d., and Lederle's liver, 45 units, q.d.

On February 1, 1947, a sternal biopsy was done. This was negative. This was repeated on May 2, 1947, and was again negative, the reason for which will be indicated shortly. Meanwhile, her blood counts had risen. By May 26, 1947, her red blood count was 1,820,000 and the white blood count was 8,300. Her bleeding time, shortly after her transfusion plus the Hykinone, had been reduced from 23 minutes and 30 seconds to 6 minutes and 40 seconds. However, her platelets which were 120,000 on January 20, had gradually fallen off until by February they were hovering around 73,500. In the meantime, the various petechiae that she had disappeared, her left ear returned to normal, her hearing returned, but she continued to show some hemorrhage in both eyegrounds.

Since we felt that this case was obviously one of a malignancy, most likely metastatic, the patient was cared for symptomatically in the hope that lethal exodus would not be too far off.

Her left eye was now completely closed by this tumor mass which had extended completely round it in the periorbital tissue. Furthermore, she now presented similar areas of tumor masses in the right orbit. The patient remained rational and there remained but one thing to do: biopsy the mass in the orbit. The question arose immediately as to whether to biopsy the mass in the left orbit, i.e., the original area, or to biopsy the little masses in the right orbit. We feared that a biopsy at this time might cause severe hemorrhage, or the wound might not heal and the cosmetic results in the end would

From the Department of Ophthalmology and Otolaryngology, The Duluth Clinic, Duluth, Minnesota.

Presented before the Minnesota Academy of Ophthalmology and Otolaryngology, June 30, 1947.

perhaps reflect upon the advisability for such a procedure, particularly from the relatives' point of view. However, a biopsy was obtained from the orbital tissue on the left on June 16. The biopsy showed: "Carcinoma simplex with occasional tendency to adenomatous arrangement of the cells . . . mitoses are commonly present." The pathological diagnosis was metastatic carcinoma.

Since the cells found on biopsy of the orbital tissue were similar in appearance and structure to those cells found in the microscopic examination of the tissue from the left mastectomy a year ago, at which time the diagnosis of carcinoma simplex was made, both orbital masses would seem to be metastatic from carcinoma of the left breast a year ago.

The patient expired the morning of June 22, 1947, having lapsed into coma twenty-four hours previously.

Postmortem examination revealed carcinomatosis of the liver, spleen, pleura, pericardium, and skin. The medullary portion of the ribs was replaced by hard yellow tissue. Section through the lumbar vertebrae showed the bodies of the vertebrae to be replaced by similar yellowish gray firm tissue. Section through the sternum showed the same type of tissue. This tissue (carcinoma) was so firm in the sternum that two previous biopsies of the sternum had failed, as has been noted previously.

MALIGNANCY OF THE GALL BLADDER ASSOCIATED WITH CHRONIC CHOLELITHIASIS

EDWIN G. BENJAMIN, M.D.
Minneapolis, Minnesota

THE purpose in presenting this case report is to focus attention on the subject of carcinoma of the gall bladder, and to briefly consider the incidence, symptomatology, treatment, and prognosis of this condition.

Case Report

The patient, a sixty-five-year-old white woman, first presented herself for treatment on June 20, 1947.

Present Complaint.—Her chief complaint was of upper right quadrant pain which had been present for about two months. The pain was almost constant and quite severe at times and was associated with anorexia, sleeplessness, and weight loss of about 12 pounds.

Past History.—Thirty years earlier she had had an hysterectomy, together with removal of ovarian tumors. No record of this procedure was available. She had had a tonsillectomy twelve years previously. She denied any other serious illnesses, operations or injuries.

History By Systems.—She had had several attacks of pleurisy—the last several years earlier. She had been troubled with cystitis occasionally but this condition was under control at the time. On close questioning, she admitted to having been troubled with "dyspepsia," associated with bloating and upper abdominal pain at times, for the past twenty years. This was never so severe as to require medical attention. She denied ever having been jaundiced. She had been constipated occasionally and took cathartics at times.

Physical Examination.—The patient was a well-developed, well-nourished white woman in no acute distress. The only positive finding of note was tenderness on deep palpation in the right upper quadrant. No mass could be felt, and the liver was not enlarged. There was no jaundice. The spleen was not palpable. The heart and lungs were normal. The blood pressure was 140/80. Pelvic and rectal examinations were negative. The urinalysis was normal. Hemoglobin was 12.5 grams.

X-Ray Findings.—A flat plate of the abdomen failed to reveal any urinary or biliary calculae. Administration of dye showed the presence of a nonfunctioning gall bladder.

Operation.—An exploratory laparotomy was performed on June 26 under sodium pentothal, ethylene, and curare. A high right rectus incision was made. The gall bladder was found to be slightly enlarged, thick-walled, with a contraction and new growth formation in the region of the neck. There was extension of the growth to the under surface of the liver. There were several nodules (metastatic) on the upper surface of the liver, one of which measured approximately 2 cm. in diameter.

The gall bladder was opened and found to contain about forty smooth faceted stones all about the same size, 5 cm. in diameter.

It was useless to attempt to remove the gall bladder as it would have involved resection of a portion of the liver to extirpate the new growth. This would have accomplished nothing in view of the presence of metastases. A simple drainage of the gall bladder was done, suturing into place a large rubber tube. A biopsy of the gall bladder wall was taken and one of the nodes from the liver was removed for study. The wound was then closed. The tissue removed showed adenocarcinoma.

Postoperative Course.—The patient left the hospital on the fourteenth day after an uneventful convalescence. There was considerable bile drainage from the tube at first but this had diminished markedly by the time of her discharge.

The patient's condition at present is precarious. She looks cachectic, she is losing weight, her hemoglobin is falling rapidly, she has no appetite and complains of extreme weakness and pain. She will shortly succumb to her carcinoma.

Discussion

The history of this case is almost typical for this condition. It will be noted that there is nothing that would lead one to arrive at a diagnosis of carcinoma. The history, symptoms, and findings are those of a benign biliary disease. There are no further x-ray or laboratory tests that could have shed any light. The most unfortunate aspect is that, although the diagnosis was established at operation, it was already too late to accomplish anything by surgical means.

There has been considerable material in the medical literature on the subject of carcinoma of the gall bladder. I wish to summarize briefly the more recent reports.

Incidence.—Carcinoma of the gall bladder may be said to comprise 5 per cent of all carcinoma deaths. It is in fifth place in frequency of incidence of carci-

Read at the annual meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 8, 1947.

noma of the organs of digestion (1. stomach; 2. colon and cecum; 3. rectum; 4. esophagus; 5. gall bladder and ducts). It accounts for 0.33 per cent of all deaths as determined by autopsy. In a combined study of 35,054 operations on the gall bladder, there were 393 carcinomas—an incidence of 1.12 per cent.

Sex.—About 80 per cent of carcinomas of the gall bladder occur in women, and it constitutes between 8 and 10 per cent of all carcinomas found in women. This greater incidence in females is considered to result from the preponderance of gallstones in women.

Age.—With rare exceptions, the patients with malignancy of the gall bladder are in the carcinoma age group. The average age is sixty years.

Causative Role of Cholelithiasis.—The great majority of cases of carcinoma of the gall bladder show the presence of stones prior to the development of the neoplasm. Most authors indicate that stones are present in about 80 per cent of cases. Several have reported cases of carcinoma developing in patients who have had stones removed but cholecystectomy was not performed. One may conclude that 4 to 5 per cent of patients having gallstones will develop cancer.

There is experimental evidence to show that neoplasms may be produced in gall bladders of laboratory animals by the introduction of foreign bodies.

Symptomatology.—The most constant symptom of carcinoma of the gall bladder is pain—usually localized in the right upper quadrant. The duration may be from a few weeks to a few months. It is dull and constant and may exist with or without colic. There is usually weight loss which depends largely on the severity of the gastrointestinal disturbance. Anorexia is almost always present. Vomiting is common, especially if there is obstruction in the duodenum. Jaundice, usually continuous, is present in about 50 per cent of cases. A mass is present in about 50 per cent of cases, as is a palpable liver edge. Nodules may be felt if there are metastases present. Anemia is not marked although it is usually present.

Differential Diagnosis.—Among the conditions to be differentiated are the following: carcinoma of the stomach, malignancy of the liver, carcinoma of the hepatic flexure of the colon, and syphilis of the liver.

Treatment.—Carcinoma of the gall bladder is usually inoperable by the time the diagnosis is made. Various authors have suggested radical procedures, depending on the location and extent of the growth. Palliative measures, especially an attempt to restore the flow of bile, should be undertaken when indicated. In most cases the removal of tissue for diagnosis has been the only procedure attempted.

Prognosis.—This can be summed up in one word—"gloomy." The majority of patients die within one year. Extension is by local infiltration of the gall bladder wall, then to the liver and ducts. Distant metastases may occur but are not common. The liver is usually involved at the time of operation. The majority of cases are of the adenocarcinoma type.

Summary

1. A typical case of carcinoma of the gall bladder is presented.

2. A brief review of the literature leads to the following conclusions:

(a) Carcinoma of the gall bladder is more common than is generally supposed.

(b) The clinical picture of carcinoma of the gall bladder is similar to that of benign biliary disease.

(c) Gallstones are probably an etiological factor in the production of malignancy of the gall bladder. For this reason, with present-day surgical methods, prophylactic removal of symptomless calculous gall bladders is justified.

(d) The diagnosis of carcinoma of the gall bladder must be made by operation, but the surgical treatment of the condition is of little value, and the prognosis is poor.

History of Medicine In Minnesota

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from February issue)

Charles H. Wagner (the name sometimes appears as Wagoner) was born at Wyocena, Columbia County, Wisconsin, on February 12, 1853. In 1860 the Wagner family removed to St. Charles, Winona County, Minnesota, where the father continued his occupations of farmer and dealer in boots and shoes. Before 1870 the family was established in Eyota, Olmsted County.

Charles Wagner received his early education in the common schools and the high school of St. Charles and in 1870 took an academic and premedical course at the University of Minnesota which he followed, in the winter of 1871-1872, with a course of study at the Homeopathic Hospital College at Cleveland, Ohio. In the spring of 1872 Dr. C. H. Wag(o)ner opened offices at the Anker Hotel in Spring Valley and there engaged in the practice of medicine until, in October, he returned to the Homeopathic Hospital College to complete his medical training; on February 12, 1873, he was graduated in medicine and surgery with an additional degree of M.F.H. for literary merit.

Returning to Spring Valley as physician and surgeon Dr. Wagner began in earnest his life in that community. On June 4, 1874, he was married to Luella F. Brown. A historical note of 1882 stated that of the four children of the marriage three were then living; that Dr. Wagner had been county physician three years and was serving as chairman of the village board of health; that he was progressive and was liberal in his professional views, not confining himself to any one school of medicine. Under the act of 1883, to regulate medical practice in the state, he received certificate No. 410 (H) on November 26, 1883.

Although Dr. Wagner is believed, with reason, to have practiced in Spring Valley into 1887, a confusing note appears that in 1881-1882 Dr. C. H. Wagner was in the little village of Money Creek, Houston County. According to another note a Dr. Wagner was in Hartland, Mower County, in the late eighties. Whatever his other moves may have been, Dr. Charles H. Wagner, long of Spring Valley, left that village at the end of the decade and before 1890 was established in Faribault, Rice County. After a few years in Faribault he turned over his practice to Dr. Charles M. Robilliard and moved to Minneapolis.

When Dr. Wagner died in Minneapolis on March 1, 1920, at the age of sixty-seven years, the *Journal-Lancet* stated that he long had been retired from medical practice.

S. W. Wallace, physician, possibly an itinerant practitioner, was in Preston, residing at the Stanwix Hotel, in 1862. His professional card ran in the *Preston Republican* from April 19 to November 7, inclusive, of that year. His name has not been found in medical directories or registers.

James Madison Wheat, one of the ten children of Silas Wheat and Eunice Dewey Wheat, was born on April 5, 1825, at Franklin, Delaware County, New York. The other children of the family (in 1943 all long since dead), were Sibyl Ann, Cordelia Eliza, George Washington, Sylvanus Addison, William Dwight, Mary Amanda, Maria Louise, Clarinda Rebecca and Lemira Frances. The father, Silas Wheat, a farmer and a native of New York State, lived to be ninety-six years old, failing by some years, however, to reach the age of his father, a sea captain who was 102 when he died. The mother, Eunice Dewey, related distantly to Admiral George Dewey, was born in Westfield, Massachusetts.

James Madison Wheat was a pupil in the district schools of Delaware County near Franklin and at the Delaware Literary Institute, the equivalent of a good high school, in Franklin. After his graduation from the Institute he went to Kentucky and there, a mere boy, taught school for eight months. On returning home he assisted in the office of Dr. Albert Sullard and studied medicine under Dr. Sullard's instruction in preparation for taking a formal medical course. He first enrolled at the Geneva Medical College at Geneva, New York, and subsequently continued his training at the Albany Medical College, Albany, New York, from which he was graduated in 1853.

Immediately after his graduation Dr. Wheat began his medical career in his native Delaware County but after a year or so, again trending to the West, he moved to Tennessee. And not long after that, in 1855, he traveled into Iowa, perhaps by way of the Mississippi River from Memphis to Dubuque. In the following winter he entered Minnesota in true pioneer style, having got a ride on a bobsleigh, he much later told his children.

In 1856 Dr. Wheat took up land in Fillmore County and established his office and home in the new little settlement of Lenora, platted around a cross-roads in northeastern Canton Township. When presently a local school district was organized, he served on the school board, and after a little red schoolhouse was built in the autumn of 1856 just south of Lenora, he was one of the first teachers. It was as a member of the board that he first met Almira Electa Foote, a native of Clinton, New York, who came to Lenora in the early sixties from Spray River, Wisconsin, to apply for the school. Dr. Wheat and Miss Foote were married on June 10, 1862; two children were born to them, James Foote and Ida May.

With the coming of the Civil War Dr. Wheat tried to enlist in the Union Army but he was rejected because of his health, which never had been robust. Tall, thin, and frail-looking, he was wiry and, more important, courageous. Throughout the period of the war he met the rigorous conditions of frontier practice, made more difficult by the national crisis, giving his time and skill freely without thought of payment, and this was always true of him, sometimes driving or riding on horseback days in succession to visit his patients when he was little able to do so. He was not an even-tempered man, but although a little irritable when fatigued, he never was ill-natured and he was known all his life as a real friend to those whom he served. In the early period of the war and at the height of the Sioux uprising in southern Minnesota, Dr. Wheat returned home after one of his longer absences to find the village

deserted, his family gone with the rest. There were hours of dismay and frantic search until he learned that the villagers had fled to the east because of an Indian scare. The report fortunately was unfounded, Dr. Wheat overtook the caravan with the good news and the settlers returned. This small but complete exodus was a favorite joke with the Wheats and other families for many years.

From the beginning of his life in Minnesota Dr. Wheat was a useful citizen. As noted, he served on the first local school board. For three years, from January, 1865, to January, 1868, he was county coroner; in 1873, at least, he was in attendance at the county poor farm in surgical cases. In 1875 and again in 1877 he (and Dr. H. C. Grover, of Rushford) was elected as a representative of the district in the state legislature, and in 1878 and 1879 and from 1881 to 1886, inclusive, he was state senator. His years in the legislature were made notable by the impeachment and trial of Judge Sherman Page, in 1878, and of Judge E. St. Julien Cox, in 1882, and particularly, in 1881, by the ratification of the constitutional amendment "The Swamp Land Act," for which Dr. Wheat long had worked, in the face of bitter opposition, and of which he was the author. The amendment provided that from the sale of the remaining swamp lands of the state a fund should be established, one half of the income from which should go to the schools and the charitable institutions of Minnesota. Of apparently little import at the time, in public opinion, the measure secured to the schools and institutions an ultimate benefit of great worth.

Medical organization began early in Fillmore County, as has been noted, and Dr. Wheat was identified with it as charter member of the Fillmore County Medical Society that was founded in the autumn of 1866, and as one of the committee to draft the constitution and by-laws and the fee bill. And on February 23, 1875, at the annual meeting of the Minnesota State Medical Society he became a member of the organization and was appointed to the Committee on Epidemics, Climatology and Hygiene. Four years later he became a member of the Committee on Finance, on which he served for the remainder of his residence in Minnesota. At the annual summer session in 1885 Dr. Wheat reported a case, of which his excellently written account is on record, of intra-uterine fibroid tumor of five years' duration and the surgical operation for removal of the growth, performed on July 8, 1884, a procedure in which he gave credit to Dr. Henry H. Haskin, of near-by Canton, who often assisted him in surgery. Dr. Wheat was versatile; he was dentist on occasion; and in cases of whatever type, he did not allow lack of especially designed equipment to be a barrier to proper treatment. Once when he had set a broken elbow joint of a small girl, he prescribed that the child should carry a flatiron (probably the kind with the handle molded into the body of the iron) in the hand of the injured arm; the advice was followed and full function of the arm and joint resulted. Under the act of 1883 to regulate medical practice in the state Dr. Wheat on May 2, 1884, registered as from Preston, obviously through a clerical error, received certificate No. 894 (R).

A constant student in his profession, Dr. Wheat read widely in other fields as well and also exercised his gift for writing poetry. He was a member of the Congregational Church and of the Masonic Blue Lodge of Preston, which he joined, it is recorded, on October 12, 1864, when he was thirty-eight years old. An excellent extemporaneous speaker who always gauged well his audience and the circumstances, he was much in demand as spokesman at weddings, funerals and other less solemn special occasions. In histories of the county

there are references to Dr. Wheat as maker of appropriate remarks at a golden wedding, as giver of a eulogy at a funeral and, in 1878, as a speaker at the initial meeting of The Old Settlers' Association of the Southern Tier of Counties in Minnesota, of which he was an organizer. And in the same histories it is written that he "probably has traveled more miles and attended a greater number of patients than any other doctor in the county." Throughout his residence in Lenora he was the only physician in the village and, whatever the conditions of his practice, he maintained home and office on his farm near by. When after many years he moved from Lenora, he was succeeded by Dr. Jay Le Roy Sackett, of regrettably brief professional career.

Although never a restless man, Dr. Wheat had a keen interest in progress, in travel and in new scenes and when, in 1883, the Northern Pacific Railway Company completed its line to the Coast, he was a passenger on the first through train "to see what is out there." It is not surprising that when the time came for a change of residence, the West was his choice. In the winter of 1886 Dr. Wheat contracted a severe cold from which recovery was tedious and unsatisfactory; knowing that he probably could not survive another severe Minnesota winter, he sold his farm home near Lenora and his other considerable property in the community and early in September, 1887, moved with his family to the newly established town of Redlands, San Bernardino County, in southern California. One lingering regret of his children, at least, even among the attractions of the new home, was the Big Spring of cold clear water in a tract of woodland that Dr. Wheat had owned between Lenora and Canton.

Dr. Wheat had intended to retire from medical practice, but the community of Redlands was young and growing and there was such urgent demand for an experienced physician that he obtained a California state license and continued his active professional life. For many years, until only a few months before his death, he was the city health officer of Redlands and was for long the secretary of the Redlands board of health. As his son has said, "He grew up again in a new place and lived to a ripe old age, active in his profession and respected by all who knew him. He gave his time and his skill for many years without regard to his own well-being."

James Madison Wheat died at Redlands on November 27, 1910, from a stroke. He was survived by his wife and the two children. The daughter, Ida May Wheat, who became an accomplished musician, died in 1918. Mrs. Wheat lived until June 25, 1933. James Foote Wheat, the son, in 1943 continued to reside in Redlands, where at different times he had served as city treasurer, county recorder, postmaster of Redlands and, more recently, president of the Redlands Real Estate Board.

A. C. White, physician and surgeon, established his office and residence in Preston in October, 1871. A Preston newspaper stated that he recently had come from Muskegon, Michigan, and that he had the confidence and recommendation of Dr. Lafayette Redmon (a practitioner of superior type) who was about to leave the county. Nothing further about Dr. White has been observed.

Alvah Fancher Whitman, who for fifteen years was to be a physician of Fillmore County, Minnesota, was the son of William H. Whitman and Malissa Green Whitman, both natives of New York State, and was born at Galway, Galway Township, Saratoga County, New York, on November 29, 1831. Wil-

liam H. Whitman, a miller, came of a family who were early in the state, as did Malissa Green. The Whitmans were of the same line as Marcus Whitman, medical missionary into the Northwest.

When Alvah Whitman was eight years old, in 1838, his parents with their young family moved into the Middle West and were among the earliest settlers in Brunswick, Shelby County and, a little later, in Sun Prairie, Peoria County, Illinois. In the local schools of these communities their five children, Alvah, Charles P., James E., Harriet M. and Nancy C. Whitman obtained their early education.

When Alvah was only fourteen years old, the sudden death of his father from typhoid fever during an epidemic of the disease left him the head of the family, and in the years of struggle that followed, his native qualities of thrift, self-reliance and self-forgetfulness developed into characteristics that distinguished him all his life. A few years after her husband's death Malissa Whitman was married to James Pettit and she moved with him and her children to Waupun, Wisconsin, where Alvah Whitman entered high school. Already intent on becoming a physician, the youth early began teaching school in order to earn money for college and by 1851 he was able to matriculate at the University of Wisconsin. There he studied for three years, but when that period came to an end his funds reached an end also and as an expedient on leaving college he joined a surveying party which was to lay out the right of way for the old Milwaukee and La Crosse Railroad from Beaver Dam to Portage, Wisconsin, and to the site of the present Hampton, Iowa. At Hampton he exchanged his transit for real estate and for a time devoted himself to farming and to teaching school.

He cherished his dream of becoming a physician and in 1862 returned to Waupun, Wisconsin, to study medicine in the office of Dr. H. L. Butterfield. Probably in the next year he entered the Medical School of the University of Michigan, at Ann Arbor, for in 1865 he was graduated with his degree of doctor of medicine. On October 2, 1865, he was married to S. Mathilda Smith, a schoolteacher, and in that autumn, at Charles City, Iowa, he began his medical career. Dr. and Mrs. Whitman had one child, who died at birth.

In 1868 Dr. Whitman settled in Spring Valley, Fillmore County, Minnesota, where for the next fifteen years he practiced medicine, in and about that village, in his own county and in neighboring counties, developing a wide and friendly acquaintance among the laity and the members of the medical profession. Some of his medical colleagues in Spring Valley in those years were, in roughly chronological order and in varying lengths of residence, Wallace P. Belden, Russell L. Moore, French W. Thornhill, Lyman Viall, Frans J. Van Mackelenbergh and Charles H. Wagner, and, early and briefly, J. J. Morey, afterward in Etna, and G. M. Pingree. Shortly after his arrival in Fillmore County Dr. Whitman allied himself with the Fillmore County Medical Society, which had been founded in 1866; he sometimes mistakenly has been listed as one of the charter members. When, in 1879, the society suspended activities, he was serving as its secretary. He became a member of the Minnesota State Medical Society in 1871 and there is evidence that he co-operated faithfully with the State Board of Health (organized in 1872).

Of fair complexion, with light brown hair and blue eyes, about five feet eight inches in height, heavy-set, free from addictions, peaceable and genial in disposition, he was well liked and has been remembered with respect. Always interested in promoting education, it was he who started the first

public library in Spring Valley, setting aside a small room in his office building for the purpose, and he helped many struggling young students, smoothing their educational and financial paths. Although his practice was general and he was considerate of old and young alike, he was devoted to children, who were very fond of him, and he was especially successful in treatment for children's diseases, bringing to his cases not only his ability as a physician but also an almost equal ability as a nurse. And although it does not always follow that a person who is gentle with his own kind is gentle with animals, Dr. Whitman valued animals and was considerate of them. He treated his horses well and enjoyed their confidence and faithfulness; during times of unusual outbreaks of sickness, which meant long weary drives into the countryside, he could not count on regular hours of sleep and therefore would doze in his carriage or his cutter, according to season, on homeward trips, trusting the horses to take him safely. And they never betrayed his trust, but jogged evenly along until they reached their own barn door, when Dr. Whitman would awake, to stable them and feed them in preparation for the next trip, soon to come.

In the early years in Spring Valley Dr. Whitman's professional card appeared in the local *Western Progress,* symmetrically spaced for harmonious effect and worded as follows: "A. F. Whitman, M.D., Physician and Surgeon. Residence, 1st house north of the Congregational Church, Spring Valley, Minnesota." He attended services at both the Congregational and the Methodist Churches and for several years taught adult classes in Sunday School. Although he did not write for publication, he had a gift for using words which he employed in compiling an account of his early life that has been preserved among the family records. Perhaps his greatest creative pleasure lay in gardening. Besides trees, shrubs, berry bushes, a grape arbor and vegetables, he had a large and beautiful flower garden laid out in the formal geometrical beds that were much admired in those days. There was none comparable in the village.

Not long after Dr. Whitman settled in Spring Valley, his stepfather and his mother, Mr. and Mrs. James Pettit, came there also to make their home. A note has been observed in a county history of 1912 that on September 16, 1881, Mrs. Pettit was seventy-six years of age.

In 1883, disposing of his home, his office building and his farm on the outskirts of Spring Valley, Dr. Whitman moved to Saint Paul, where he continued to practice; his residence was on Dayton Avenue. On December 28, 1883, under the medical practice act of that year, he received state certificate No. 488 (R). In this period of his life he became a member of the Ramsey County Medical Society and for a time served as its necrologist. He attended the Plymouth Congregational Church and later the People's Church of Saint Paul.

Alvah Fancher Whitman died in Saint Paul on December 21, 1913, a few days subsequent to a stroke, in his eighty-second year. Mrs. Whitman survived until August 22, 1919.

G. M. Willis was a pioneer physician in Fillmore County. In the autumn of 1866, then a resident of the village of Carimona, in Carimona Township, he was one of the founders of the Fillmore County Medical Society and at the organizational meeting in the office of Dr. Redmon of Preston, on October 17, was elected corresponding secretary of the group. Other mention of Dr. Willis has not been noted. In 1867 and 1868, as recorded in *The Minnesota*

Railroad and River Guide, G. M. Willis, perhaps the same man, was postmaster in Rushford, Carrolton Township.

A **Dr. Wilson** was in Chatfield, Fillmore County, from the early sixties well into the seventies, according to sparse evidence. The *Preston Republican* of February 5, 1864, announced, "Dr. Wilson of Chatfield is in town," and in a commercial register of the summer of 1872 there was listed Dr. ——— Wilson of Chatfield, apparently a fair business risk. As far as inquiry has been possible to the writer, Dr. Wilson does not live in the memories of Chatfield citizens. There seems possibility, if not probability, that the Dr. Wilson of Chatfield and Dr. Henry L. Wilson (H. Wilson), sometime of Carimona and Preston, were the same.

Henry L. Wilson (usually H. Wilson), came to Carimona, Carimona Township, it has been said, in the fifties and there practiced medicine for about seven years. Sometime in the middle sixties, again hearsay, Dr. Wilson left Carimona, perhaps left the county, but after some years he returned and opened an office in Preston. After a few months in that village he moved permanently and "his last years were spent in the new southwestern Minnesota, where he died. He was considered a very competent physician for his time."

Fortunate access to some early newspapers of Fillmore County and of Olmsted County gave a few notes that helped in piecing together a story of this physician. In August, 1864, Dr. Wilson, of Carimona, was appointed assistant surgeon in the Sixth Minnesota Regiment of Volunteer Infantry, in which Wallace P. Belden of Spring Valley was a senior surgeon; the two men received their appointments on the same day in St. Paul and traveled homeward together as far as Rochester. Dr. Wilson served with the regiment until August 19, 1865. When, on October 17, 1866, at Preston, the Fillmore County Medical Society was organized, as stated previously, Dr. Wilson, still of Carimona, was present and was appointed a member of the committee, with Dr. J. M. Wheat and Dr. A. H. Trow, to draft the constitution and by-laws and a fee bill. Although his name did not appear again in notices concerning the society, he was in the county into the winter of 1867, as evidenced by official record of his remuneration to considerable amounts for attendance on paupers. On January 12, 1867, however, the *Rochester Post* announced that Dr. H. Wilson, "formerly surgeon of the sixth regiment," had called on the way to Saint Paul, where he intended to locate for the practice of his profession. "He abandons a large and paying practice in Fillmore County, and with his acquirements, experience and established reputation as a surgeon is sure of a successful career at the capital." On March 9, 1867, the *New Federal Union*, of Rochester, stated that Dr. Wilson had established himself at Dundas, Rice County, where he had bought a first-class drugstore. The next news of him came in the *Preston Republican* of February 12, 1869, in which it was announced that he had resumed the practice of medicine in Fillmore County, in the village of Forestville, and that he would be ready at all times to attend the wants of the afflicted. Forestville is about four miles southwest of Carimona and is in Forestville Township, which borders Carimona Township on the west. Two weeks later the editor of the paper added to Dr. Wilson's official announcements the statement that Dr. Wilson had returned to the county and that "he has all the business he can attend to."

It was on May 3, 1869, as nearly as can be established, that the Fillmore County Eclectic Medical Society was organized in Preston at the office of Dr. Orson A. Case, and it was then that Dr. Wilson, evidently eclectic in thought, transferred from the Fillmore County Medical Society to the new group. In this year and for a time in 1870 he served as president and as such he requested the secretary, Dr. J. W. Eighmy, to forward copies of the proceedings to the county newspapers and to the *Chicago Eclectic Medical Journal.*

Dr. H. Wilson, according to his professional cards, was still in Forestville into November, 1870. Announcement of his removal to Preston or elsewhere was not noted, but it seems probable that sometime in the early seventies he went into southwestern Minnesota. Under the Affidavit Law of 1887 Dr. Wilson received an exemption certificate. As late as 1890 he was in Woodstock, Pipestone County.

O. Wold, with offices on Jessie Street, was practicing medicine in Rushford around 1869-1870. His name was observed in a business directory of the period but not in any medical directory.

Fordyce Worth, a resident of Hesper, Winnesheik County, Iowa, a village about two miles below the Minnesota state line and directly south of Mabel, Newburg Township, Fillmore County, was by citizenship a physician of Iowa, but beginning in 1870 his practice extended well into Fillmore County, Minnesota. Long before the village of Mabel (founded in 1885) existed and, in fact, long before any resident physician of Fillmore County lived in the community, Dr. Worth was a trusted physician in that region. (Dr. Charles W. Cady settled in Mabel in 1892; Dr. A. P. Lommen began to practice there in 1895; and Dr. Hildus A. O. Nass came in 1898.) Today, the remaining pioneer citizens of the community, some of them now residents of Mabel, associate Dr. Worth definitely with their early history. For that reason biographical notes concerning him are included here.

Fordyce Worth was born on December 9, 1831, at Starkboro, among the hills of northeastern Addison County, Vermont, the son of a farmer. His mother, whose maiden name was Carpenter, was American born, the daughter of a Quaker family. When Fordyce Worth was seventeen years old and after he had received his early education in the local schools, he went to Mt. Gilead, Ohio, where he served for two years as an apprentice in a machine shop. The next three years he spent in the lumber trade in Wisconsin. By that time, 1853, having determined on the profession of medicine, he began his medical study, probably under a preceptor, and presumably he continued thus for the next several years. In 1856 he bought property in Winnesheik County, Iowa, and there opened a general store. In 1859, it has been said, he went to Chicago to the Bennett College of Eclectic Medicine and Surgery. Either his medical education was interrupted further and for a long time or there has been error in the recording of dates, for he was graduated in 1870; it seems likely that he matriculated in 1869 and took his degree the following year; a formal course of a year was usual at the time, especially if a student had for a considerable period worked under a preceptor.

After his graduation in 1870 Dr. Worth settled in Hesper, and in October, 1871, succeeding Dr. W. C. Battey, Hesper's first postmaster, Dr. Worth was appointed to the office, which he held for the ensuing twenty-seven years. In 1886, under changing laws of medical practice, he was licensed as a physician in Iowa and on February 25, 1887, he received Minnesota license

No. 1310 (E). He was a Mason (A. F. and A. M.), a member of the Decorah Lodge No. 181, and a member of the Modern Woodmen of America.

In 1856 Fordyce Worth was married to Sattie Keyes, a native of Ohio, at Muscatine, Iowa. There were two children of the marriage, Alice and Henry. A vivid little picture of Dr. Worth has come down the years from a Christmas when his children yet believed in Santa Claus; to aid illusion the doctor made large and convincing tracks in the snow up and down the shed roof which led to the chimney, and correspondingly through the yard, to suggest that the reindeer had been waiting just outside.

After his wife's death, in 1886, Dr. Worth was married for the second time, in 1888, to Dr. Louisa Day, who was born in 1850 and who graduated from the Bennett College of Eclectic Medicine and Surgery in 1879. From Hesper, Dr. Worth and Dr. Louisa D. Worth together carried on their large medical practice which extended, as has been noted, into Fillmore County, Minnesota.

Dr. Worth survived his second wife and he continued his medical practice until about 1918, when ill health forced him to retire. When he died in March, 1920, he had for some three years been making his home with his son, R. Henry Worth, of La Crosse, Wisconsin. His daughter, Alice Worth Edmunds, had died previously. In 1943 Mr. R. H. Worth continued to reside in La Crosse.

Do we "idealize the doctor some?"

DONALD BANNERMAN PRITCHARD (1865-1931)

An unsigned article, *History of Medicine in Winona County,* which appeared in *Minnesota Medicine* in 1940, unfortunately did not include a biographical sketch of Dr. Donald Bannerman Pritchard, of Winona. Therefore the following sketch, which originally was prepared as part of *Notes on the History of Medicine in Fillmore County,* because of Dr. Pritchard's early residence in Rushford, is presented now.

Donald Bannerman Pritchard, who was to become one of the distinguished physicians of Minnesota, spent the first two years of his professional life as an able practitioner in the village of Rushford, Fillmore County, and the ensuing forty-two years in Winona, Winona County.

Born at Fort Garry (Winnipeg), Canada, on February 19, 1865, Donald Bannerman Pritchard was the son of Samuel Pritchard, an English Episcopal minister, and Johanna Bannerman Pritchard, of Scotch birth. The Reverend Mr. Pritchard and his family were early settlers in the Winnipeg district, which was under the domination of the Hudson's Bay Company; the five children were Donald, Adelaide, Robert, Charles and Ida. In 1943 the only member of the group living was Adelaide (Mrs. Richard Goodrich) of California.

Educated in academic subjects at St. John's School and College, an Episcopal institution in Winnipeg, and in medicine at the University of Edinburgh, Scotland, where he studied four years, Donald B. Pritchard was graduated at Edinburgh in 1887. In after years he took postgraduate work in Philadelphia. On his return to America, Dr. Pritchard was licensed by examination to practice in Minnesota, receiving certificate No. 1370-1 (R) on April 20, 1887, and he at once settled in Rushford. On October 27, 1891, he was married to Mary E. Hanson, an American girl, of Rushford. The two children of the marriage were Helen B. Pritchard (in 1943 registrar at the Winona State Teachers College) and Margaret, who died on November 4, 1930.

In 1889, shortly after moving to Winona, a larger town than Rushford and situated advantageously on the Mississippi River, Dr. Pritchard became a member of the Winona County Medical Society. Note should be taken of

his paper, "The Contagiousness of Tuberculosis," that he presented on admission to the group. Written thus early in his medical career, it was original and of striking text on a moot subject, and it aroused spirited and acrimonious argument among a group of mature physicians. In the fifty years and more that have elapsed since that reading, only one statement in the exposition of his theory and conclusions has failed of confirmation; namely, that a perfectly healthy individual would not contract tuberculosis and that "it is only after the health has become below par from the many influences that may bring about such a result that it is possible for the bacillus to find a resting place." In recent years, at a meeting held under the auspices of the Buena Vista Sanatorium to honor Dr. Pritchard's memory, that paper again was presented, and it was discussed from the standpoint of its wisdom and lasting value.

A general practitioner and surgeon, Dr. Pritchard practiced independently in Winona for one year and then entered into partnership with Dr. J. B. McGaughey, with whom he remained until Dr. McGaughey died in 1908. In 1901 a firm known as "The Associated Physicians and Surgeons" was organized, in which Dr. Pritchard and Dr. J. B. McGaughey were associated with Drs. E. D. Keyes, N. S. Lane, H. M. Lichtenstein, Oswald Leicht and H. F. McGaughey. This firm continued for several years. Later Dr. Pritchard again practiced alone, occupying offices with Dr. Lichtenstein. In 1930 and 1931 he was associated in practice with Dr. L. I. Younger.

Dr. Pritchard lived a useful life, a moving spirit in professional and civic progress. He was a member of county, state and national medical associations and of special professional groups. The first physician of Winona to become a Fellow of the American College of Surgeons, he was also a member of one of the national standing committees of the College. Chief organizer of the Winona General Hospital, which was established in 1894, he was largely responsible for obtaining funds for construction of the hospital buildings, and he served continuously as a member of the board of trustees until his death in 1931. When the executive committee of the hospital board was organized, he was its first chairman, and thereafter its secretary; he was also president of the hospital staff for many years and was an instructor in the nurses' training school of the hospital. Dr. Pritchard served as city health officer of Winona from 1907 to 1919 and in that time brought about many vital improvements in administration. He is recognized as the originator of the present city health department. For a number of years he was on the Board of Health of Winona County as well. For six years, during four of which he was its president, he was a member of the Board of Education of Winona.

Dr. Donald Bannerman Pritchard died in Winona on September 22, 1931, survived by his wife and his daughter. In tribute to him, the Winona *Republican Herald* published editorials, from which much of the foregoing information was drawn and from which the following excerpt was taken:

> It would be unfair to other Winonans to say that Dr. Pritchard built the Winona General Hospital, or that he was the individual responsible for Winona County's fine system of modernized highways, but it is proper to state that Dr. Pritchard was the energetic force that made Winona realize these needs and crystallized public sentiment into concrete action. Today these and other attainments of this Winonan may appear to be simple natural developments in community life, but that conclusion is the evolution of the idea. The pioneering that Dr. Pritchard persistently did for these humanitarian necessities was as hazardous as was the building of the first house on the Winona prairies. It required vision and energy to combat popular sentiment and leave the path of least resistance. The hospital building, and the ribbons of concrete and other fine highways that cross this county are demonstrations of how this Winonan attained his visionary goals.

President's Letter

NO FIRMER FOUNDATION

"A profession has for its prime object the service it can render to humanity; reward or financial gain should be a subordinate consideration."

Thus begins the statement of the Principles of Medical Ethics, Section I, Chapter 1, formulated by the American Medical Association. Medicine, one of the highest professional callings, can have no better nor firmer foundation. It is by the closest adherence to this principle that the profession should be able to withstand any man-made threats to its prestige and its freedom.

One such challenge to the sincerity of the medical profession has come with the extension of the services of the government in providing for the social welfare and security and the entrance of a third party into the doctor-patient relationship. This third party is the agency, which supported by taxes or public funds, pays for medical care for such groups as the indigent, the aged, the blind or disabled, veterans and inmates of correctional institutions. Non-government agencies and other organizations have come into existence which also provide care for certain groups of persons.

This third party poses a major problem which the medical profession must solve. Physicians must provide constructive leadership so that high-type medical care is assured all persons who come under the jurisdiction of the various agencies or who look to these agencies for help in meeting the cost of needed medical care.

A specific problem which requires close co-operation between the profession and the agency is that of the establishment of a fair and equitable schedule of fees. Most of the schedules arrived at by the various agencies have been fair; seldom have they been excessive; and, of course, sometimes they have been quite low. The feeling of responsibility for those unable to pay is strong in the physician, and when the patient is indigent, most physicians render adequate service regardless of fee. This is most commendable. This service is, in fact, the cornerstone of the profession's public relations. At the same time, no reasonable person expects the profession to assume full responsibility for *every* indigent patient. By working together physicians and agencies which they serve can arrive at agreements that will be satisfactory to both.

It is the occasional resorting to dishonorable practices and the use of devious methods to increase fees that must be eliminated if the good name and good will of the entire body are to be safeguarded. If a small minority of the profession is allowed to continue in its efforts to get the most possible for the least amount of effort when the third party pays the bill, private medicine's high aims will fall short of achievement and its objectives will be seriously challenged.

That must not happen. Petty self-interest has no place in medicine. If in the past physicians had allowed themselves to place personal gain before duty to the patient and to the public, medicine could never have achieved its present eminence nor its record of accomplishment. Medicine was founded on service to mankind and all of its organizational activities are

directed to the improvement of that service. Physicians worthy of the name ask themselves not "What will I get out of this?" but "How can I best serve?"

The personal integrity of every member of the medical profession is its best weapon against the political quackery which today threatens the world. In our own country, congressional miracle workers are constantly propounding new cure-alls for the people's ills. The formulas, however, always have the same basic ingredient—compulsory health insurance. The latest preparation of these do-gooders is labeled S.1320—a bill to provide a federally-administered national health insurance and public health program.

The bill represents a philosophy foreign not only to doctors of medicine but to the country as a whole. It would mean the entrance of government into still another field—that of the private practice of medicine—and it would edge the country one step nearer totalitarianism. Who can stop the government from practicing medicine. The answer is YOU, Doctor.

We have agreed that some form of insurance is one way to meet the cost of illness; but we debate whether compulsion should have a part. If we maintain that compulsion should not enter the picture, then we must show that the voluntary method will work. The voluntary prepayment medical care program is the godchild of organized medicine. It is up to physicians to see that it has every opportunity to grow and develop to the limit of its possibilities.

This is going to mean some sacrifice on the part of the medical profession, together with a firm resolve to place the common good above personal gain. Men of medicine should by reason of their fibre be able to meet this challenge. We can meet the requirements of any program which the government has set up by co-operating as far as possible with agencies providing medical care. We can also make voluntary health insurance work.

It's up to us now. We have a chance to prove ourselves. Let us make the most of it.

PROPOSED BLUE CROSS-BLUE SHIELD MERGER

THE information broadcast in the January 19 issue of *Time* that Dr. Paul R. Hawley, recently resigned medical director of the Veterans Administration, had been appointed the administrator of the Blue Cross-Blue Shield merger on a national basis, came as a surprise. The announcement was made by Roy E. Larson, president of Manhattan's United Hospital Fund and former director of the New York Blue Cross, at a joint Blue Cross-Blue Shield dinner held in Washington, January 10. The assumption seemed plausible that all the Blue Cross and Blue Shield organizations, the former with 29,250,000 and the latter with a membership of 7,250,000, had effected a national organization.

The announcement in view of the facts seems unaccountable. No such merger exists. As a matter of fact, meetings are being held in March to consider the advisability of such a step. So far a report of a subcommittee of the Blue Cross-Blue Shield committee, including tentative by-laws, was approved February 3 by the Blue Cross Commission, and the proposal was discussed at a joint meeting held in Chicago March 6 and is to be considered at a meeting of the Blue Shield Commission in Los Angeles, March 26 and 27.

There are those who believe it would be a distinct advantage to the growth of both Blue Cross and Blue Shield plans if the two organizations were to be combined on a national scale to provide uniform policies and procedures and to facilitate insuring on a wider than state basis. The thought too has been expressed that such an organization might be of value in contacting governmental agencies in the hospital and medical care of the indigent on a state or national basis.

Notwithstanding the advantages of such a merger of hospital and medical insurance plans, the proposal has already met strongly voiced opposition and is likely to meet still more. The following appeared in an editorial in the March issue of *Northwest Medicine:*

"Announcement of a 'merger,' when in fact there was no merger, struck many western doctors as resembling an effort to stampede such a merger by presentation of what might be accepted as a *fait accompli* by the uninformed or unthinking. Actually, it has come to be considered nothing but a brazen attempt, using the prestige of Dr. Hawley's recent success with the Veterans Administration, to accomplish at the national level what has repeatedly failed or been rejected at lower levels."

Recently, representatives of Blue Shield plans of California, Oregon, Idaho, Montana and Utah met in San Francisco and drew up resolutions to the effect, in brief: (1) that inasmuch as Blue Shield plans are the responsibility of the medical profession, any national merger should recognize the parity of the Blue Cross and Blue Shield groups; (2) that any encroachment by the Blue Cross or any similar institution into assumption of responsibility for prepaid medical care in the United States is undesirable and must be stopped, and (3) that an independent national insurance corporation which upon formation would thereupon be in competition with other commercial insurance companies on a national scale is undesirable and should not be created. Finally, they consider the proposed merger on a national basis undesirable and at variance with the best interests of the future of voluntary medical care plans in the United States.

A perusal of the by-laws of the proposed merger indicates that, if adopted, there is little evidence that the medical profession would have much voice in determining policies of the new association. Individual Blue Shield organizations, while operated by members of the AMA and state medical associations, are separate and distinct organizations. The organized profession has received little or no consideration on the part of those who have been trying to effect this merger. It is not difficult to see that the proposal involves the formation of a powerful national organization which may take control of the Blue Shield plans out of the hands of the medical profession.

NATIONAL PHYSICIANS COMMITTEE

ON the evening of February 27, 1948, representatives from many of the county medical societies of the state met at the Lowry Hotel, Saint Paul, to hear of the activities of the National Physicians Committee and of the need of such a medical publicity organization to counteract the insidious propaganda which is being conducted by socialists and communists alike to undermine our economic system. Socialists favor the ultimate socialization of all industry, and medical practice heads the list. The communists constitute a political party taking its directions from a foreign government and have the avowed purpose of destroying our form of government by any means, including violence. There are only too willing to aid the socialists in their aims.

Dr. Louis A. Buie's President's Letter, which appeared in our November, 1947, issue, contained a complete statement of the commendable record which the NPC has made during the past decade in publicizing the truth about medical practice in these United States and the subversive activities of communists and so-called "social reformers" in their efforts to destroy the American way of life. Any member who has not read that President's Letter should do so.

There has been some uncertainty on the part of some of our members as to the status and even as to the need of such a publicity organization as the NPC. It was organized by some outstanding members of the AMA, who saw clearly the need of united action to counteract the activities directed towards the undermining of medical practice and private enterprise in general. Members of the NPC are all outstanding members of the AMA, and many have given generously of their time and talent to the activities of this organization. It may have been felt by some physicians that with the establishment of the Committee on Medical Service of the AMA there was less need for the NPC. This is not the case. While the Committee on Medical Service is doing valuable work in the furthering of medical insurance and keeping in touch with legislation, anyone who heard the NPC representatives, Ed. Stagen and Arthur L. Conrad, depict the astounding and widespread underhanded activities of the communists in our country must have realized that there is more to do than the Committee on Medical Service can possibly accomplish alone. The facilities of the NPC enable them to go much farther in the ferreting out of communistic activities which are permeating educational institutions and affecting the youth of our country in the colleges and even grade schools.

Those representatives from the various county societies who attended the February 27 meeting, called by Dr. Ed Hayes of Minneapolis, constitute the State Committee co-operating with the NPC. All who were present must have been impressed by the seriousness of the threat, not only to medical practice but to individual freedom in our country. They will doubtless carry the message to their county medical societies and present the goal of every society member, a member of the NPC to their confreres. Not only can the members of the profession do their part by supporting the NPC financially, but in their contacts with the laity and as members of school boards can fight the communistic and socialistic underhanded propaganda which has found its way not only into school textbooks but into a number of organizations which innocently or underhandedly give their aid and support.

GASTRIC RESECTION VERSUS VAGOTOMY

RECENTLY, the results of surgical procedures for treatment of peptic ulcer at the University of Minnesota have been reviewed. In this investigation 416 consecutively operated cases of peptic ulcer were considered. The mortality in elective cases was 2.9 per cent. The operation recommended consists of at least 75 per cent resection of the stomach, followed by a retrocolic anastamosis with the jejunum at the duodenojejunal junction producing a short afferent loop with inversion of the lesser curvature in the Hofmeister pattern. The recurrence rate of ulcer after this operation was less than 1 per cent. There are probably few series in which so many cases have been reported, the mortality as low, and the cases so carefully studied. There is no question but that the experimental work of Wangensteen and his co-workers concerning the pathogenesis of peptic ulcer is the most comprehensive and conclusive to date.

Within the past few months, two surgical journals have devoted several articles to the question of vagotomy in the treatment of duodenal ulcer.[1,2] The rationale of vagotomy is that it decreases gastric tone and the amount and degree of gastric

acidity. There is some experimental clinical evidence to show, however, that within a year or two after vagotomy, the fasting acidity and motility of the stomach readjust themselves to denervation and return to normal values.

Most surgeons perform vagotomy through a transabdominal approach, by which route the vagus can be completely sectioned in 80 to 90 per cent of cases. While one can be surer of cutting all the vagal fibers through the transthoracic approach, the fact that the transabdominal approach permits examination of the ulcer is a decided advantage. There is no question but that duodenal ulcers in some instances heal following vagotomy and the patients become symptom free. How permanent this healing is, no one can say at present. Some ulcers heal even after a gastroenterostomy, but it is generally agreed that the frequent development of jejunal ulcer following this operation makes it undesirable. Just what patients should be subjected to vagotomy is not clear. Certainly vagotomy should not be resorted to in the treatment of gastric ulcer. One must review the cases of ulcer treated by vagotomy as critically as those treated by gastric resection. If, with time, it can be proved that patients with duodenal ulcer treated by vagotomy have permanent healing with a low incidence of recurrence and complications, it may be the operation of choice. In the meantime to be sure of curing a complicated gastric or duodenal ulcer, gastric resection is the procedure of choice.

CHARLES E. REA, M.D.

CANCER CONTROL PROGRAM QUESTIONNAIRE

Three thousand eight hundred and eighty-one questionnaires concerning the reaction of the physicians of Minnesota to Cancer Control Programs of various types were mailed out recently and there was a 52.7 per cent return. Dr. N. O. Pearce of the Health Department is to be congratulated on the success of this enterprise. Accuracy was sacrificed somewhat for simplicity since the participants were asked if they would endorse the projects listed, and they did not have an opportunity to express neutrality or complete objection. The responses were tabulated according to their source: Twin Cities, Duluth, Rochester, cities with a continuation of courses on cancer for physicians with 25,000. The Cancer Committee of the Minnesota State Medical Association wishes to interpret the replies to this study.

There was an overwhelming response in favor of continuation of courses on cancer for physicians with tuition and expenses paid. The total of 85 per cent of those responding endorsed this project with a somewhat lesser percentage favoring the University as the site of these courses and a two-day duration of the course with both clinical demonstrations and lectures as the method of choice. One-day medical educational projects given in scattered local areas should be given a further trial.

Forty-nine and six tenths per cent endorsed a free correspondence consultation service on cancer cases for physicians. The Cancer Committee felt that this project should be instituted in the near future in co-operation with Dr. Carl Drake, editor of MINNESOTA MEDICINE. Further announcements may be in the offing.

The profession decidedly favored employing qualified physicians to talk on cancer to medical societies and hospital staffs, 63.9 per cent endorsing the project. This falls in the realm of the Speaker's Bureau Committee which already has a list of physicians available for this purpose. The Cancer Committee favors an honorarium of $50 to $100 and expenses for these speakers.

On the question, "Shall we employ cancer specialists to hold free cancer detection clinics in local hospitals, quarterly or other intervals with referral of cases to private physicians?" 40 per cent of the profession endorsed the project. Since employing "cancer specialists" is quite objectionable to many physicians, the Committee felt that this particular type of cancer detection clinic should not be promoted. However, in the light of the great success of the one-day cancer detection clinic held at Fergus Falls, these clinics should be held in any location where a local County Medical Society feels that they are indicated.

A total of 40.3 per cent endorsed the provision for cancer information centers. In the only community where these have been tried, Duluth, 61 per cent of the physicians endorsed the project. It was felt that physicians should conduct the information centers if county medical societies wished to promote this project for their communities.

There was a surprising 63.3 per cent favoring the promotion of more adequate cancer facilities and services to assist the practicing physician. This was broken down into surgical, x-ray, radium, pathologic and hospital services. There was no agreement as to where improvement was needed except in pathologic services, where 47.3 per cent endorsed an improvement in this field. It is to be pointed out to the profession that physicians specializing in pathologic diagnosis of biopsy material are in the private practices of medicine and have previously voted unanimously not to accept any money for this service for indigent cases. The establishment of a pathologist in smaller centers depends upon his earning power in that locale. Interference with the biopsy source of income would seriously interfere with this eventual and ideal development in medical practice in Minnesota as it already has in other states. It was agreed that the pathologists should concede to some form

of subsidy in the cases of indigent and near indigent patients since many additional biopsies would be taken by physicians if there was a method by which patients would not have to pay directly for this service.

The Cancer Committee felt that the present facilities for training public health nurses in the field of cancer were adequate since there was only a 38.3 per cent endorsement of continuation courses on cancer for public health nurses.

There were 59.9 per cent favoring the provision of talks and motion pictures on cancer for lay people. However, only 47 per cent endorsed wide distribution of printed matter to lay people. The Committee felt that the benefits of lay education on cancer far outweighed any theoretical injurious effects of the procedure.

X-RAY SURVEY

A program of chest x-raying that will extend into 1951 is now in full operation by the Minnesota Department of Health, under the supervision of Dr. Hilbert Mark, director of the Division of Tuberculosis.

The program involves the use of three mobile x-ray units. Many of the surveys cover entire counties. During 1948, one unit is being used to x-ray the population of Benton, Sibley, Polk, and Beltrami Counties, rural Stearns County, part of Winona County, and part of the city of St. Cloud; another is now completing the St. Cloud and Winona County surveys and will later be used for Dodge and Marshall Counties. This unit will also be used to x-ray the Indians of Red Lake and White Earth Reservations and Mahnomen.

The third unit started in January an x-ray survey of students in colleges of the state; also all inmates of state institutions. It is expected that these two surveys will be repeated each year. The same unit will be used later this year in Nicollet County and during the summer in Washington County. The survey of colleges and state institutions will be resumed next October.

Up to the end of 1947, a total of 214,326 persons had been x-rayed, in addition to those included in the Minneapolis, Saint Paul, and St. Louis County surveys. Chest x-ray surveys conducted by the State Department of Health have been completed in Blue Earth, Steele, Freeborn, McLeod, Isanti, Carlton, Morrison, Wadena, Todd, and Kittson Counties, and requests for surveys have come to the Department from sixty-one additional counties. Partial surveys have been done in Dakota County (West St. Paul and So. St. Paul), Crow Wing County (Brainerd, Crosby, Ironton, Deerwood, and Pequot Lakes), Washington County (St. Paul Park and Cottage Grove), Western Stearns County, Polk County (Crookston, Fertile, and East Grand Forks), and Norman County (Ada). A calendar of surveys for 1949, 1950, and 1951 is now being prepared.

Persons found by the surveys to have any pathological condition of the chest are referred to their own physicians for advice and treatment.

SILLIMAN'S VISIT TO MINNESOTA

Benjamin Silliman was in many ways a remarkable man, for he not only introduced the teaching of the laboratory sciences at Yale University (and through this example his influence spread to many other American colleges), but he was responsible for first promoting instruction at the graduate level. The Sheffield Scientific School, which he helped to found, became the first American graduate school; and Yale, through the Scientific School, granted the first Ph.D. degrees ever to be awarded in this country.*

The Sheffield Scientific School fostered the practical application of the sciences at a time when we were expanding our natural resources and were acutely in need of technically trained manpower. Mr. Joseph E. Sheffield of New Haven, who endowed the School, was responsible for pushing the Rock Island Railroad through to the Mississippi River, completing the road in 1854. In celebration of this event, Benjamin Silliman and a party of Mr. Sheffield's friends (some 700 of them) were given a free excursion from New York to Rock Island in private trains. The party then proceeded in a fleet of river boats up the Mississippi to Saint Paul. The following extracts from Silliman's diary describing the frontier village as it was then and his visit to the Falls of St. Anthony are most interesting. The day before had been spent on Lake Pepin.

June 8, 1854. Arrival at St. Pauls, Minnesota (2,000 miles above the Gulf of Mexico; 744 [above] St. Louis). After the repose of a quiet night we had hardly time to finish our breakfast before we espied St. Pauls, the capital of Minnesota.

As the town stands on a high bluff, it is conspicuous at a distance and makes a very handsome appearance. It was said at the time of our visit to contain 5 to 6 thousand inhabitants—now in 1862 doubtless many more. Large warehouses, several churches and a spacious and elegant capitol, half a mile from the town, would hardly permit one to believe that a man to whom we were introduced built the first house in 1849.

Our passengers were soon on shore and ranging about the town. We, Mrs. Silliman and myself, did not go to a hotel but regarded the steamer as our home. In the evening the Governor and citizens gave a reception to Ex-President Fillmore and to members of the excursion. Mr. Fillmore is reported to have made an excellent speech and Mr. Bancroft, the historian, a very good one. There was also a ball and those who attended spoke in high terms of the ceremonial. *We* were too much fatigued by an excursion to the falls to attend the public assemblies and were glad to pass our evening quietly in the *War Eagle* not now agitated by moving engines.

Excursion to the Falls of St. Anthony. On our landing we found carriages standing in readiness for us. In connexion with an agreeable party we occupied a stage with four horses. We rode 9 or 10 miles over good roads wide and hard and passed an extensive prairie—a splendid tract of land—the greater part of which was fenced and under successful cultivation. Cattle and horses were numerous and in this region they are large and of superior breed. The general aspect of the country was inviting altho' in the latitude of the northwest part of Lake Superior.

Minnesota State Medical Association
George Earl, M.D., Chairman

CONSEQUENCES OF END OF HEALTH PROGRAM FOR MIGRANTS FEARED

(The dissolution of the health service program for migrant agricultural workers may have serious consequences to the medical profession and the public-at-large. This is the opinion of physicians who have carefully studied the program just ended last December and the federal proposals for the care of foreign workers in the future. It is recommended that members of the medical profession keep themselves informed of developments, and to provide physicians with an opportunity to examine the facts, the following article has been prepared by Dr. J. A. McElligott and Mr. C. B. Hoff, medical director and executive director, respectively, of the Midwestern Agricultural Workers' Health Association, which has its headquarters in Milwaukee, Wisconsin.)

The Midwestern Agricultural Workers' Health Association was formed to give medical service to the indigent migrant agricultural workers who were ineligible for medical welfare services in the various states because they lacked residential qualifications. Implementing it was the U. S. Department of Agriculture which had federal funds for this service.

In the spring of 1943, a conference was called by Dr. Franklin S. Crockett in Chicago during the time the House of Delegates of the AMA was in session. At this informal gathering were representatives of the Farm Security Administration (U. S. Department of Agriculture) and doctors from all over the United States including Dr. W. A. Coventry of Minnesota. The government representatives explained that they wanted to form a non-profit corporation to provide health care for Jamaican workers who, by agreement between governments, were to receive free medical care while they were in the United States harvesting vitally needed crops. In this conference the organizational structure and policies of the proposed organization were shaped after full discussion by the group.

The association or corporation was to be patterned after similar associations which had rendered service to small segments of the migrant population in other regions of the United States. However, the finished fabric was strictly a Midwestern tailored job. In June, 1943, three physicians and three laymen were selected as incorporators and members of the policy making board of directors. One of the lay members of the board had agreed to serve until the Michigan State Medical Society delegated another physician as a board member. The association was incorporated under the laws of the state of Indiana and registered to operate in Minnesota, Iowa, Illinois, Wisconsin, Ohio, Michigan, Kansas, Nebraska, Missouri, Kentucky, and the Dakotas. Shortly afterward a grant of federal funds was made.

Ideas New to Midwest

As new as the idea of corporation disbursing federal funds through a board of four delegates of organized medicine and three laymen might have been to midwestern medicine, the techniques of providing services to a scattered floating population was newer. At the first meeting of the board, it was resolved that services were to be rendered by private practitioners and hospitals on a fee for service basis. Negotiations were to be started with each of the twelve medical societies and liaison maintained with them in order to embody the suggestions of organized medicine into the operating plans. The patient was to have free choice of physician when more than one was available in the rural areas. Although the association was to have a physician as medical director, he was not to intrude between patient and doctor. Also at the very first meeting, it was decided that, although government funds financed the association, and some government employes were on the board, the association was not to be used for the advancement of alien philosophies of medical practice. The board adopted a rather positive attitude against the hiring of physicians on a salary basis to maintain the services, be-

cause the agreements with the Jamaican government provided that the workers receive the same care as the American population of comparable status received. The board interpreted this to mean good medical care, not cheap medical care. It is imperative to make it clear that the board of directors was nobody's rubber stamp from the very beginning. As time passed it entered more and more into the operations of the association. The board hired an executive director who was provided an executive committee of the board for assistance in making emergency decisions between board meetings.

In the peak year of operations, the association employed about sixty full or part time persons, mostly nurses, to administer the program for the 22,000 eligible workers in the twelve states. In that area over 4,000 doctors and hospitals rendered service to the workers at a cost of about $1.50 a worker for each month of their seasonal stay in the Midwest. It appears at this time that the costs of administration will be somewhere between ten and twelve per cent. The costs compare favorably with the cost of identical services elsewhere in the United States for the same kind of workers, even though the MAWHA did not hold the physician and hospital to a definite schedule of fees or limit the amount of diagnostic or therapeutic work done for a patient. Through the state medical societies, the association asked that vendors of service give the association the benefit of local relief rates, and they did, although no one in the association slavishly adhered to the rule in checking accounts. Early in the first year's operations it was found that in no two states and in few localities of the same states were the problems the same or the administrative solutions identical.

Peak of 2,500 Migrants Reached

Minnesota had 2,500 workers, Jamaican and Mexican nationals, during its peak year. There were foreign workers in the state for six months of the year although the numbers did not remain constant from month to month. They worked mostly in the southern part of the state and in the extreme western part of the state. In the latter location they harvested grain, but the larger group was employed in the southern Minnesota canning areas. Within these areas, 324 Minnesota physicians or hospitals were paid $42,203.09 for service rendered to eligible workers. It should be stressed that these figures refer to government transported workers only, as the association did not generally provide care for the far more numerous domestic migrant workers.

Early in the program the supervising nurse concluded an agreement with the major canning companies that the plant industrial nurse could give nursing services to workers who were housed in the canning company camps. This service is familiar to a good many Minnesota physicians.

A good many people think of the migrant as a war-time phenomenon. This impression is strengthened because during the war the government entered into the recruitment and transportation of workers, and health services were given largely to such transported workers, while self-transported workers were not given service except as under very restricted circumstances. It is well to think of the foreign and government transported worker as a wartime substitute for the domestic worker or at least a reinforcement for him.

Government Ends Program

As of December 31, 1947, the government program for the recruitment and transportation of workers came to an end. As a result, all migrant indigent agricultural laborers and their families will receive no more health care from the government. Although the majority of them are non-residents of the state, local doctors, hospitals or welfare agencies will again be forced to assume the burden of caring for these people unless some legislation is enacted to lift the burden from state taxpayers and professional charity. Some think that the interstate worker is a federal charge.

During the past five years certain federal agencies were very active in studying conditions among the migrant workers. The Federal Interagency Committee on Migrant Labor published a 58-page bulletin last March. On page 29 of the bulletin, this paragraph appears: "The committee is of the opinion that financial and administrative responsibility for insuring adequate health and medical facilities for migrants should rest with public health authorities—state and federal—not with employers and their seasonal workers. It, therefore, recommends that a well operated health services program for migrants be provided and that federal grants-in-aid be made to health departments to assist them in the

development of such services. Removal by the states of residence requirements as a condition for such benefits is a prerequisite."

This recommendation, if enacted into law, puts the migrant worker into a privileged position, for it absolves the seasonal worker from financial responsibility for his health care. Secondly, this recommendation takes the worker out of the Department of Agriculture health program and puts the United States Public Health Service and the state health departments into the business of administering and financing a curative medical care program for American families. On pages 45-46 of the bulletin, suggested standards for health services for labor camp occupants are set forth. At the crucial center of this suggested setup is the so-called "clinic or health center" in each camp where over a hundred migrants were housed. The physician operating this center shall give preventive and curative services and treat all cases of illness which can be handled adequately with clinics on an ambulatory basis.

Step Toward Compulsion Feared

One need not be a hysterical alarmist to see in these recommendations a pilot program which could serve as an excellent training ground for administrators of a compulsory health program for the general population. The writers and others who served on the board of directors of the MAWHA gained familiarity with this pattern of medicine because USPHS administrators constantly urged MAWHA to turn over to health departments some of the work done by private physicians and to hire doctors on an hourly basis to give service on the camps. The board stuck to its guns. The MAWHA followed suggestions of the Minnesota State Medical Association. Service was rendered by private physicians on a fee for service basis.

Organized medicine has logical grounds on which to base its suspicions of "Washington planners." Federalization of migrant health as recommended in the above quotation is not the only solution for good health service to migrants. The non-profit organization such as the MAWHA in which organized medicine and the migrant each have delegated representation on the policy-making board of directors is more likely to give the migrant health services on par with those enjoyed by the local resident than federal or state medicine could give. MAWHA medicine was identical to care received by the average Minnesotan because Minnesota physicians gave the care in Minnesota private hospitals using Minnesota methods of practice without the intrusion of a federal or state employe between patient and doctor.

The MAWHA as a corporation still exists. In the near future Minnesota physicians might be called on for a decision. The only question will be: "Does Minnesota want federal and state medicine for its migrants or does Minnesota want to give its care through the non-profit organization that has been doing it for five years?"

MAWHA THANKS MINNESOTA DOCTORS

On February 9, the following letter was received at the State Office, addressed to the physician members of the Minnesota State Medical Association:

Gentlemen:

On behalf of the board of directors of the Midwestern Agricultural Workers' Health Association and its staff, I wish to thank the State Medical Association of Minnesota and its practitioner members who gave service to the foreign and domestic migrant laborers during the past five seasons.

The Congress of the United States has terminated the foreign labor program and our contract with the United States Government ends as of December 31, 1947, although the corporate entity of the MAWHA has been preserved.

Our board of directors, consisting of four doctor-delegates from Midwestern medical societies and three laymen, resolved to keep the corporation intact because we felt that a non-profit corporation of this kind has proved its ability to operate, with the assistance of organized medicine and its practitioners, a program of health care for migrant agricultural laborers economically and efficiently through the use of rural practitioners on a fee-for-service basis, with free choice to the patient in areas where a choice of doctors is available, and with regard to the ethics and scientific principles advocated by organized medicine.

Each year your state society has given me a report on the operation of the MAWHA within your state. These reports were helpful to the board of directors and the staff in planning methods of operation.

With the termination of our contract with the government the indigent migrant worker could very well become a subject of the charity of doctors and hospitals for, by lack of residential qualifications, he is ineligible for medical relief in the communities in which he tarries for a while in the harvest season. It is entirely possible, however, that some legislation will be enacted to relieve the smaller communities of the burden of caring for ineligible workers out of local taxpayers' funds.

The Midwestern Agricultural Workers' Health Association, by keeping its corporate identity can probably offer its facilities and service to government and organized medicine alike in any program for the emergency medical relief of the indigent, or near indigent, migratory agricultural worker in areas where his pay is insufficient to meet his needs.

Very truly yours,
F. S. Crockett, M.D., *President*
Board of Directors, MAWHA

SCHEELE SUCCEEDS PARRAN AS USPHS SURGEON GENERAL

On April 6, Dr. Leonard A. Scheele, present director of the National Cancer Institute, will become surgeon general of the United States Public Health Service, succeeding Dr. Parran.

A letter from the Washington Office of the Council on Medical Service of the American Medical Association gives a brief biographical sketch of Dr. Scheele.

Born in Fort Wayne, Indiana, July 25, 1907, Dr. Scheele was educated in Michigan, receiving his M.D. in 1934 from Wayne University in Detroit. He entered the Public Health Service almost at once. He held several field positions; did cancer control work and was transferred to civilian defense. Later he was assigned to the Army and served in Sicily, Italy and Germany. He received many decorations for his foreign service.

He returned to the National Cancer Institute in 1946 and was made director in 1947. He and his wife, who is a dentist, live in Bethesda near the Institute. They have three children.

According to the Washington Office, Dr. Scheele is an intense worker, probably partial to research. Their bulletin states that he has shown outstanding ability as an administrator and is thoroughly aware of the potentialities of his new position.

Parran Aware of Replacement

Dr. Parran knew he would not be reappointed, according to the *Washington Report on the Medical Sciences,* another periodic bulletin of medical news issued from Washington. In the February 16 report, some interesting background of the present situation is given.

It seems Dr. Parran would have liked to serve another four years, but because Federal Security Administrator Ewing likes to enunciate his own health policies and Dr. Parran is himself an independent thinker, reappointment seemed unlikely. Evidently, Ewing plans big things for the formulation of President Truman's national health program. The medical science report says it will be "extremely interesting" to see what Dr. Scheele will be able to accomplish within the pattern cut out by Ewing, since Ewing has given every evidence of desiring to be his own Surgeon General by forming health policies which have formerly been the function of the head of the USPHS.

Dr. Scheele, who is forty, will be the youngest Surgeon General in his country's history, it is reported. He hasn't much seniority in the list of commissioned officers in the health service; and it appears the Dr. Parran helped name his successor, whom he says is "one of the outstanding public health figures in this country," possessing "both personal and professional qualities to be a great surgeon general."

Minneapolis Woman Placed on Two-year Probation Term for Criminal Abortion

Re. State of Minnesota vs. Elizabeth L. Libera

On February 13, 1948, Elizabeth L. Libera, thirty-two years of age, 3551 North 4th Street, Minneapolis, was sentenced by the Hon. Arthur W. Selover, Judge of the District Court of Hennepin County, to a term of not to exceed two years in the Women's Reformatory at Shakopee. Because of the fact that there was no evidence of other abortions, Judge Selover placed the defendant on probation for two years. Mrs. Libera had previously entered a plea of guilty on January 12, 1948, to an information charging her with the crime of abortion.

Mrs. Libera was arrested on December 21, 1947, following the hospitalization of a twenty-four-year-old unmarried Minneapolis woman suffering from the after effects of a criminal abortion. The defendant performed the abortion by means of a catheter and was paid the sum of $200 for her services. The defendant stated to Judge Selover that she was married and the mother of three children. She further stated that she had never performed any other abortions except one on herself.

Minneapolis Woman Must Serve One Year for Criminal Abortion

Re. State of Minnesota vs. Lola Wilkie

On February 13, 1948, Lola Wilkie, fifty-nine years of age, 717 19th Avenue South, Minneapolis, was sentenced by the Hon. Frank E. Reed, Judge of the District Court of Hennepin County, to a term of two to eight years in the Women's Reformatory at Shakopee. The Court stayed the sentence and placed the defendant on probation for five years; Mrs. Wilkie, however, must serve the first year of the sentence in the Minneapolis Women's Detention Home. The defendant had previously pleaded guilty on December 1, 1947, to an information charging her with the crime of abortion.

Mrs. Wilkie was arrested on a complaint issued October 27, 1947, charging her with performing an abortion on an unmarried Minneapolis girl on September 7, 1947. The abortion was performed by the defendant at the home of the patient by means of a catheter. The patient became ill and was subsequently hospitalized at a Minneapolis hospital. The defendant Wilkie has a long

criminal record dating back to 1928. On October 3 of that year the defendant entered a plea of guilty in the District Court of Hennepin County to an information charging her with the crime of receiving stolen property and was sentenced to serve ninety days in the Minneapolis Workhouse. On May 22, 1945, the defendant was sentenced in the District Court of Hennepin County to serve one year in the Women's Reformatory at Shakopee following her plea of guilty on April 20, 1945, to an information charging her with the crime of abortion. The defendant served that sentence. On February 28, 1941, the defendant was indicted by the grand jury of Hennepin County for the crime of abortion, but the warrant of arrest was not served on her due to the fact that the sheriff's office was unable to locate the defendant. However, that indictment was called to the attention of the Court at the time Mrs. Wilkie was sentenced on May 22, 1945.

The defendant stated to the Court that she was born on July 7, 1888, at Necedah, Wisconsin. She stated that she became involved in doing abortions many years ago when she took care of abortion patients for a chiropractor, now deceased.

Former Masseuse Sentenced to Ramsey County Jail for Criminal Abortion

Re. State of Minnesota vs. Pauline L. Schultz

On February 16, 1948, Pauline L. Schultz, seventy-four years of age, 656 North Lexington Avenue, Saint Paul, Minnesota, was sentenced by the Hon. Gustavus Loevinger, Judge of the District Court, to a term of one year in the Ramsey County Jail. Mrs. Schultz had entered a plea of guilty on February 2, 1948, to an information charging her with the crime of abortion. Judge Loevinger stated to the defendant at the time sentence was imposed, that notwithstanding her age and the condition of her health, the defendant would not be placed on probation but would be required to serve her sentence. The Court pointed out that the investigation made by the probation officer disclosed that Mrs. Schultz had been doing abortions over a long period of time.

Mrs. Schultz was arrested on December 13, 1947, by Saint Paul Police officers following an anonymous telephone call to the Police Department advising them that a woman was having an abortion performed by the defendant Schultz. The police officers placed Mrs. Schultz' home in surveillance and discovered the abortion patient entering and leaving Mrs. Schultz' place. The patient was removed to Ancker Hospital where she disclosed that Mrs. Schultz inserted a catheter for the purpose of producing a miscarriage. The patient stated that she paid Mrs. Schultz $150 for her services. When police officers arrested Mrs. Schultz, they found $6,350 in currency in Mrs. Schultz' home. A statement was taken from Mrs. Schultz in which she admitted performing the abortion in the instant case, and also that she had performed five or six other abortions during 1947.

Mrs. Schultz, prior to 1931, was licensed as a masseuse. She also had represented herself to the public at various times as a chiropractor and as a naturopathic physician. Mrs. Schultz was acquitted by a jury in the District Court of Ramsey County in April, 1928, of the charge of abortion. In May, 1931, Mrs. Schultz was indicted by the grand jury of Ramsey County for the crime of manslaughter in the first degree, following an alleged criminal abortion. That indictment was nolled by the Court on October 26, 1931, because of the lack of sufficient evidence to connect the defendant with the crime and partially because of the failure of a Saint Paul physician to co-operate with the State in the prosecution.

Saint Paul Woman Sentenced to One-year Jail Term for Criminal Abortion

Re. State of Minnesota vs. Bessie Moulton

On February 20, 1948, Bessie Moulton, fifty-eight years of age, 188 E. 15th Street, Saint Paul, Minnesota, was sentenced by the Hon. Gustavus Loevinger, Judge of the Ramsey County District Court, to a term of one year in the County Jail. Mrs. Moulton, on January 30, 1948, had entered a plea of guilty to an information charging her with the crime of abortion. The matter was passed at that time to permit the case to be investigated by the probation officer. Following that investigation, Judge Loevinger advised the defendant that she would have to serve her sentence.

Mrs. Moulton was arrested on January 17, 1948, by Saint Paul police officers following an investigation made by the Minnesota State Board of Medical Examiners, the Minneapolis Police Department and Saint Paul police officers. That investigation disclosed that a 22-year-old Minneapolis girl had been aborted by the defendant. Following the abortion, the patient became ill and was removed to a Minneapolis hospital. The investigation further disclosed that Mrs. Moulton was paid $100 for her services and that she had performed numerous other abortions over a period of several years.

Mrs. Moulton was born at Oxford, Wisconsin, and lived in Detroit, Michigan, prior to coming to Saint Paul twenty years ago. Mrs. Moulton admitted a previous conviction for a violation of the Federal liquor laws during the days of prohibition, for which offense Mrs. Moulton served eight months in the Ramsey County Jail. Mrs. Moulton stated that she performed a few abortions in Detroit before moving to Saint Paul and that she had done some abortions in Minneapolis as well as in Saint Paul.

TREATMENT OF CONGESTIVE HEART FAILURE

(Continued from Page 266)

probably not necessary) was followed by complete disappearance of his anasarca.

Between May and December of 1947 this man was kept edema free without use of diuretics, and only returned monthly for observation. No decrease in size of his heart has been demonstrated. Vital capacity is still definitely reduced, but by following his diet rigidly, he is able to do light work and is now self-supporting.

Conclusion

Digitalis is still the most important single drug in the management of heart failure.

Diuretics relieve those congestive symptoms which may remain after digitalization.

In severe dropsy the Schemm regime is very much worthwhile.

Minnesota Academy of Medicine

Meeting of November 12, 1947

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club, Saint Paul, on Wednesday evening, November 12, 1947. Dinner was served at 7 p.m., and the meeting was called to order at 8 p.m. by the president, Dr. E. M. Hammes.

There were fifty-four members and three guests present.

Minutes of the October meeting were read and approved.

Dr. Harold S. Diehl read the following Memorial to Dr. Robert Green and a motion was carried that this be spread on the records of the Academy and a copy sent to the family.

ROBERT G. GREEN, 1895-1947

Thirty years ago, while serving as an instructor in the Department of Bacteriology, I had as one of my assignments the teaching of a course in general bacteriology to students from the College of Agriculture. I well remember the keen interest, the enthusiasm and the outstanding performance of a student in that class by the name of Robert Green.

Last year I received from this former student a bound volume of some fifty reprints of selected scientific papers with the following inscription on the flyleaf: "It is just thirty years ago that a student asked you in the hall if you thought that it would be worth while for him to try to do a little research in bacteriology. This book is a record of what has happened so far as a result of your encouragement." It was signed Robert G. Green.

Shortly after accepting this volume, it was my privilege to recommend the appointment of Dr. Green as head of the Department of Bacteriology of the University of Minnesota. Unfortunately he served in this capacity for only a few months before his sudden death about two months ago. But even in this brief period of time his vision, his enthusiasm and his inspiring leadership had given new life to a department which only recently had suffered the loss of such distinguished scientists as Dr. Arthur Henrici and Dr. Winford Larson.

In scientific work one rarely finds an individual of the originality of mind and the research genius which Dr. Green possessed. Over the years, Dr. Green's major scientific work was in the field of viruses, but his 200 scientific papers cover a variety of subjects. Some of his early papers were on the physical chemistry of bacteria. Distemper and canine encephalitis claimed his major interest for several years, with the development of an effective vaccine against each of them. Then he described and discovered the cause of a new disease which he called Chastek paralysis. To me it has always seemed that Dr. Green's studies of tularemia and other diseases of the wildlife population are monumental contributions to our knowledge not only of these diseases but also of the course of epidemic diseases under natural conditions.

During the past few years, Dr. Green had been devoting his research interests primarily to cancer and to infantile paralysis. The members of this Academy will remember his presentation here last winter of his hypothesis as to the nature of cancer and of the investigative work which seemed to lend support to this theory. Sortly before his death Dr. Green brought to my office a series of test tubes showing precipitin tests which he believed could lead to a serological diagnosis of cancer and even to possible immunization against cancer. His work on infantile paralysis was directed toward the development of a vaccine against this disease.

To have the life of such a brilliant scientist cut off at the very peak of his career is an irreparable loss. But his achievements, which far exceeded those of most investigators in a complete lifetime, remain to serve as the stepping stones upon which further progress along these pathways will be made. And the ideas which he has planted in the minds of his students may well blossom forth into greater accomplishments even than he envisioned. Truly, it has been a privilege to have had Dr. Green as one of our group.

HAROLD S. DIEHL, M.D.

September 8, 1947

The following were elected as candidates for active membership in the Minneapolis list: Dr. Malcolm Hanson, Dr. Carl Laymon, and Dr. H. M. N. Wynne. Dr. Donald Creevy's name was transferred from the Minneapolis list to the University Faculty list.

The scientific program followed. Dr. R. M. Wilder, of the Mayo Clinic, Rochester, Minnesota, read his inaugural thesis.

SAMPLING THE NUTRITION OF MINNESOTA CHILDREN

RUSSELL M. WILDER, M.D.
Rochester, Minnesota

The achievement represented by the synthesis of a number of the vitamins is one of the many brilliant contributions to scientific medicine to which we have been witness in this century. However, the commercialization of these products has involved exaggeration and misstatement so distasteful that some scientists in medicine have acquired an actual antipathy to vitamins. Food consumption studies, especially those conducted in 1938 by the Bureau of Home Economics of the United States Department of Agriculture,[5] suggested that a

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

very large proportion of the people in this country were ill fed, and prompted a campaign to improve nutrition. Some of us believe that this campaign contributed to the waging of the war. It also added fuel, however, to feed the flame of vitamin exploitation, and in consequence of all this emphasis on vitamins a wide rift has developed between those who do and those who don't believe that vitamin deficiency is prevalent in this country. The divergence of expressions of opinion on this subject, but especially the exploitation of synthetic vitamins, has been harmful to the program to improve the public health through providing better diets. An English speaker once remarked: "The sincere friends of freedom [he could have had the same to say about the friends of better diets] have been few, and their triumphs have been due to auxiliaries whose objectives often differed from their own; and such association, which is always dangerous, has sometimes been disastrous by giving opponents just ground for opposition."

There must be a middle ground, and of course there is, one to which the conscientious student of nutrition has adhered despite the overemphasis of the vitamins on the one hand and the deaf ears of skeptics on the other. My personal attempt to pursue this middle way has been a pilgrim's progress.

Like many a physician I had been unwilling to accept estimates of the incidence of malnutrition which were based on food consumption surveys. Few patients coming to the Mayo Clinic appear to be malnourished, and for almost every case of malnutrition some reason other than the diet appears to be the explanation. Especially disturbing to me were reports some years ago that diabetes mellitus could be caused by deficiency of thiamine. I put this to the test and was almost gleeful when it could be shown that varying the intake of thiamine of severely diabetic patients was without effect on requirements for insulin. This study, made by Doctors K. A. Smith and H. L. Mason,[4] led to further investigation of thiamine deficiency. The later studies were begun by Dr. K. A. Smith, but were carried further with great elaboration by Dr. Ray D. Williams and associates.[7-11] The results upset my earlier complacency, for it was demonstrated that a thiamine intake no smaller than what the food consumption studies showed to be the thiamine content of many diets could produce a metabolic abnormality in persons who had been normal metabolically. When glucose was given to these persons, intermediates of glucose oxidation accumulated in the blood. Although lactic and pyruvic acids are found in normal blood, the amounts of them rose to abnormal levels when glucose was administered. In some persons this abnormality was accompanied by an increase in the sugar of the blood and some glycosuria. This was diabetes of a kind, but not diabetes mellitus. It was correctable by giving thiamine although not by giving insulin.

Associated with this metabolic abnormality were some psychologic and neurologic disturbances that were nonspecific and hence unimportant diagnostically, and yet were quite disabling.[6] These disabilities, like the metabolic defect, developed in the periods of thiamine deprivation but disappeared when the thiamine content of the diet was increased to levels now considered to be adequate. The studies referred to were begun in April, 1939. In that same year riboflavin deprivation was reported[3] to have caused thinning and fissuring of the epithelium of the lips (cheilosis), reddening and cracking at the angles of the mouth (angular stomatitis), a type of seborrhea in the creases at the sides of the nose (dyssebacia), congestion of the circumcorneal plexus of the conjunctiva, reddening of the tongue with changes of the papillae of the tongue, and other tissue lesions. These objective abnormalities, like the metabolic defect produced by deficiency of thiamine, were accompanied by the development of subjective disabilities, with recovery when riboflavin was restored. Likewise, at about this time, nicotinic acid, now called niacin, was found by Elvehjem[2] to be specific for the treatment of black tongue, the disease of dogs analogous to human pellagra. Niacin proved equally effective in the treatment of the lesions of the skin and tongue of patients with pellagra. Also niacin, riboflavin and thiamine, given together, in therapeutic trials were shown in several clinics to help relieve other signs and symptoms presented by persons who had been diagnosed for years as suffering either with pellagra or with pellagra without the photosensitive lesions of the neck and hands characteristic of pellagra—so-called pellagra sine pellagra.

With these discoveries clamoring for attention and with war around the corner and threatening to worsen the quality of the food supply, it would have been the height of folly in 1940 and 1941 to fail to take a stand for improvement of the nation's diet; improvement especially with respect to the vitamins which the food consumption surveys showed to be supplied in very limited amounts by many diets. The campaign started with the backing of a committee of the National Research Council composed of physicians, biochemists, physiologists and others who had special training in this field. The Food and Nutrition Board, as the committee came later to be called, was largely instrumental in securing, among other things, improvement of white flour and bread through their enrichment, increased consumption of milk, in-plant feeding arrangements for workers in war industries, and some degree of differential distribution of the food supplies.

The small part I had to play in these activities of the Food and Nutrition Board was accomplished, I must admit, with considerable uncertainty about the extent of the problem with which we had to deal. How many people really needed such attention to their diets? The Board established certain standards; we called them recommended dietary allowances for calories, protein, iron, calcium and each of several vitamins. The allowances admittedly were something more than minimal requirements. They were intended as a goal which if attained would assure that all would be well fed. It was recognized in this that individuals differ in their needs and that a minimal requirement for one would represent inadequacy for another. Now the food consumption surveys showed that many diets fell below the allowances recommended, but it was not known that this discrepancy was actually reflected in extensive failure of nutrition. Few medical surveys of nutritional

status had been made; indeed, no agreement had been reached as to what could be accepted as criteria of malnutrition.

Because of this dilemma I was very pleased to be invited to join a medical mission to study and evaluate nutritional conditions in Newfoundland. To judge from all accounts available, that was a country which undoubtedly was ill fed. Actual beriberi, actual scurvy and night blindness had been reported as occurring not infrequently in its inhabitants. What would be the incidence there of the several tissue lesions reputed to be characteristic of less severe deficiencies? The medical survey made in Newfoundland has been reported.[1] It revealed a very high incidence of the tissue lesions looked for. Unusually satisfactory colored illustrations of many of these lesions are contained in that report, together with a more complete description of the lesions than is necessary here. The survey further showed a large proportion of the population to be suffering with those vague disabilities which had been encountered in pellagra and in subjects who had been deprived experimentally of thiamine and riboflavin. The major errors in the diets of these people were deficiencies of vitamins, and I returned from Newfoundland convinced that vitamin allowances as low as those obtaining there were decidedly unhealthful. I still remained uncertain as to whether many persons in our country were similarly affected, especially in regions such as Minnesota where supplies of milk, meat, greens and citrus fruits are more abundant. I therefore welcomed a later opportunity to study groups of children in this state and to compare the incidence of tissue lesions found in them with the incidence of the lesions found in Newfoundland.

Surveys in Minnesota

The Minnesota study involved examining grade school children in each of three communities: the first the White Earth Indian Reservation, the second a rural area of Wabasha County in southeastern Minnesota, the third a district of Rochester inhabited by a population which included many of the families of my colleagues of the Mayo Clinic. In Newfoundland, vitamin assays of the blood had been obtained. The techniques for these were not available in the Minnesota study, and in any case such assays provide at most an index of the adequacy of the recent diet. Instead, in Minnesota we had food consumption data acquired by questioning the children. In Newfoundland 846 persons of all ages had been examined. Of them 402 were children of grade school ages, 193 boys and 209 girls. They alone are taken here for comparison with the Minnesota children. The Newfoundland survey was made in August, 1944. The distribution by locality of the Minnesota children, the sex in each of the three groups and the month of the year in which they were examined were as follows:

White Earth Indian Reservation, thirty-seven boys, fifty-two girls, examined in September, 1945.

Wabasha County, fifty-three boys, thirty-six girls, examined in December, 1945.

Rochester, fifty-one boys, thirty-eight girls, examined in January, 1946.

TABLE I. FOOD SUPPLY OF NEWFOUNDLAND PER CAPITA DAILY NUTRIENTS

Nutrient	Recommended Allowance*	Newfoundland Consumption	
		Quantity	Recommended Allowances Per Cent
Calories	2,544	2,997	115
Protein	66.1 gm.	88.4 gm.	134
Iron	11.8 mg.	9.5 mg.	**80**
Calcium	960 mg.	415 mg.	**43**
Vitamin A	4,590 U.S.P. units	1,443 U.S.P. units	**31**
Ascorbic acid	71.3 mg.	20 mg.	**35**
Thiamine	1.20 mg.	0.90 mg.	**75**
Riboflavin	1.60 mg.	1.03 mg.	**65**
Niacin	12.0 mg.	15.0 mg.	125

*Revised 1945; weighted allowances per capita.

The children were taken without selection and in each group were fairly equally distributed between the ages six to fourteen years.

Food Consumption Data

Newfoundland.—The major part of the food supply of Newfoundland was imported. The local food production comprised a very small amount of meat, eggs and milk, a large catch of fish, mainly cod which were eaten dried, and a small yield of garden products, consisting for the most part of potatoes, cabbages and turnips. From this data we could estimate that the caloric allowance was adequate, that the protein allowance was adequate, but that the average diet was far below the recommended allowances with respect to calcium and the vitamins (Table I).

Some doubt attaches to the figures given for the adequacy of niacin. In diets lacking milk and meat, except for the dry codfish which constituted the principal source of animal protein in Newfoundland, the requirement for niacin may be considerably higher than that which is called for in the recommended dietary allowances.

The reliability of these estimates was supported by the finding of high values for serum protein and reasonably good values for blood hemoglobin in all but a very small percentage of the 370 persons whose blood was examined, and by low blood values for ascorbic acid, vitamin A and riboflavin in more than half the persons. Small excretions of thiamine in the urine suggested that the intake of thiamine was less than adequate in 40 per cent of the population.

White Earth.—The dietary habits of the children on the Indian Reservation were studied by Miss Irene Netz, nutritionist of the State Relief Agency. The contribution to the total calories made by flour, sugar and fat was very large, and although the consumption of potatoes was also large, that of meat and of green or yellow vegetables and milk was small. The large majority of the children received a lunch at school, but even so, the average intake, although probably superior to that in Newfoundland, was certainly inadequate in several nutrients. The diets appeared to be satisfactory with respect to calories, less so with respect to animal protein, but definitely low in calcium and low in vitamins.

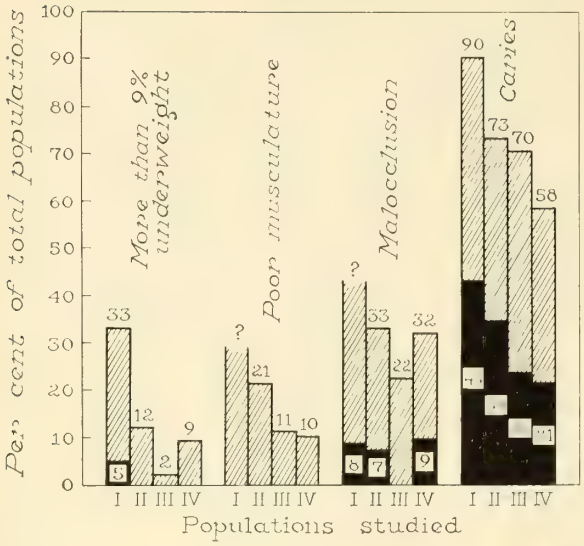

Fig. 1. Incidence of abnormalities observed in children of (I) Newfoundland, (II) White Earth, (III) Wabasha County and (IV) Rochester. Solid black indicates incidence of lesions of severity.

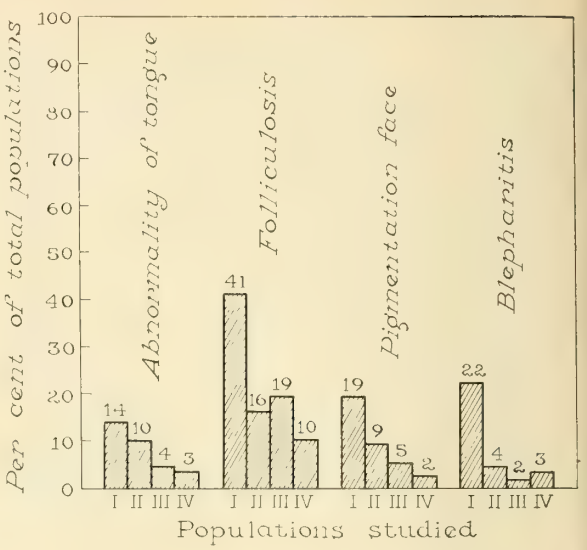

Fig. 2. Incidence of abnormalities observed in children of (I) Newfoundland, (II) White Earth, (III) Wabasha County and (IV) Rochester.

Wabasha County.—The diets of the children in the Wabasha County schools was regarded by Miss Netz as fairly typical for the children of southeastern rural Minnesota. A tenth of the children used no milk, a fourth used less than one serving daily of meat, fish or poultry, a half used no citrus fruit and only 60 per cent obtained a satisfactory amount of fresh vegetables. Bread, sugar and sweetened foods contributed excessively to the total calories. School meals had not been served. The diets of many of these children, although ample with respect to calories and protein, provided considerably less than the recommended allowances of calcium and the vitamins.

Rochester.—The diets of the Rochester children were certainly superior on the whole to those of the children of rural Wabasha County. Nevertheless, many of these diets could have been improved, and about 10 per cent were clearly less than what is recommended with respect to fruits, vegetables and milk. School meals were not provided.

Here are four groups of children for comparison. In every group the diets are adequate with respect to calories and probably with few exceptions adequate with respect to protein and iron. The difference between the diets of the groups is in respect to calcium and the vitamins provided, with the incidence of inadequate diets unquestionably greatest in Newfoundland, least in Rochester.

Findings on Examination

The examination of the children was limited in each instance to measurement of height and weight, to palpation of the muscle and inspection of the skin of the arms and legs and to inspection of the face, the scalp, the conjunctiva, the lips, the gums, the teeth and the tongue. No instruments were used other than a hand slit lamp, a dental probe with a flattened tip and a tuning fork.

Height.—There were no striking differences in stature. The heights even of the children in Newfoundland, where the incidence of poor diets unquestionably was highest, showed very close conformance to the Baldwin-Wood standards for children of the ages represented. Deficiencies of calcium and vitamins of the degrees encountered in these populations are apparently without effect on skeletal growth, this being strikingly in contrast to what is regularly reported from regions where protein and calories are lacking.

Weight.—Body weights for age and height differed strikingly. The incidence of children 10 or more per cent below the average standard weight for height and age was 33 per cent in Newfoundland, 12.4 per cent in White Earth, 2 per cent in Wabasha County and 9 per cent in Rochester (Fig. 1).

Poor Musculature.—Poorly developed musculature was conspicuous in the majority of the children of the Newfoundland group. Among the White Earth children poor musculature was observed in 21 per cent, whereas in Wabasha County and Rochester the incidence was 11 per cent and 10 per cent, respectively (Fig. 1).

Malocclusion of the Teeth.—No record was made of the incidence of malocclusion of the teeth in Newfoundland. It is my recollection that it was very high. The incidence of this abnormality in White Earth, Wabasha County and Rochester was 33, 22 and 32 per cent, respectively (Fig. 1).

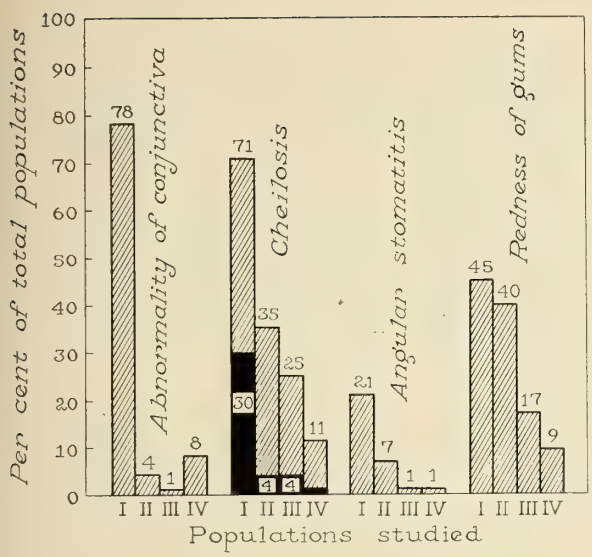

Fig. 3. Incidence of abnormalities observed in children of (I) Newfoundland, (II) White Earth, (III) Wabasha County and (IV) Rochester. Solid black indicates incidence of lesions of severity.

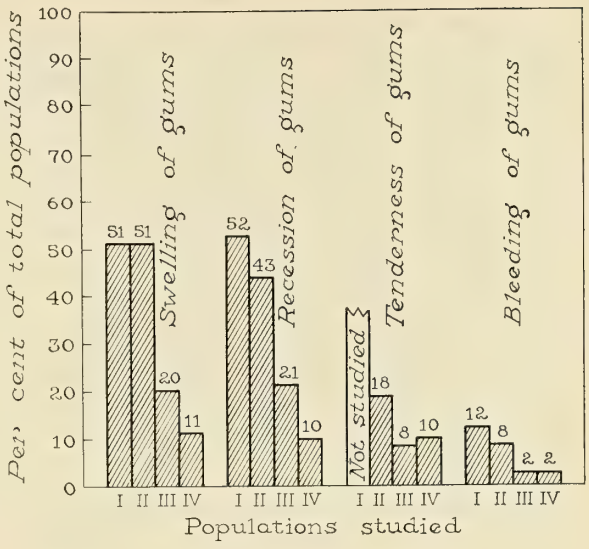

Fig. 4. Incidence of abnormalities observed in children of (I) Newfoundland, (II) White Earth, (III) Wabasha County and (IV) Rochester.

Dental Caries.—The incidence of dental caries of all degrees was 90 per cent in Newfoundland, 73 per cent in White Earth, 70 per cent in Wabasha County and 58 per cent in Rochester. The incidence of caries affecting four or more teeth was 43 per cent in Newfoundland, 34 per cent in White Earth, 23 per cent in Wabasha County and 21 per cent in Rochester (Fig. 1).

Folliculosis of the Skin of the Arms and Legs.—The incidence of the lesion of the skin variously designated as permanent gooseflesh, or folliculosis, or keratosis pilaris was 41 per cent in Newfoundland, 16 per cent at White Earth, 12 per cent in Wabasha County and 10 per cent in Rochester. It is difficult to ascribe this fourfold difference to heredity. The lesion is more conspicuous in the winter season, but the survey in Newfoundland was made in August and that in Rochester in January (Fig. 2).

Pigmentation of the Face.—This abnormality is encountered in caloric deprivation. It also is observed in deficiencies of vitamins. The caloric supplies were adequate in these children and yet the incidence of suborbital and circumoral pigmentation was 19 per cent in Newfoundland, 9 per cent in White Earth, 5 per cent in Wabasha County and 2 per cent in Rochester (Fig. 2).

Blepharitis.—Swelling and redness of the eyelids was noted in 22 per cent of the Newfoundland children. The incidence of this lesion was inconspicuous in all three groups of Minnesota children (Fig. 2).

Abnormality of the Tongue.—The incidence of increased redness of the tongue with various degrees of abnormality of its papillae was 14 per cent in Newfoundland, 10 per cent in White Earth, 4 per cent in Wabasha County and 3 per cent in Rochester (Fig. 2).

Conjunctival Abnormality.—The incidence of loss of luster and thickening of the conjunctiva was very high in Newfoundland, but low in all three of the groups of Minnesota children (Fig. 3).

Cheilosis.—Reddening, thinning, scaling and chapping of the epithelium of the lips was present in 71 per cent of the Newfoundland children and in 35 per cent of the children at White Earth. The incidence in Wabasha County and Rochester was 25 per cent and 11 per cent, respectively (Fig. 3).

Angular Stomatitis.—Various combinations of erythema and open fissuring at the angles of the mouth have been observed when deficiency of riboflavin was severe. Such lesions appeared in 21 per cent of the children in Newfoundland, in 7 per cent of those at White Earth and in 1 per cent of those in Wabasha County and Rochester (Fig. 3).

Gingivitis.—Redness, swelling and recession of the gums with or without unusual tenderness or bleeding was noted in about half of all the children in Newfoundland and White Earth, in about a fifth of the children of Wabasha County and in a tenth of those in Rochester (Fig. 3 and Fig. 4).

Concluding Comments

Several other abnormalities were observed in these several groups of children, but the point of interest is that the incidence of many of the tissue lesions mentioned descends progressively from Newfoundland to Rochester in inverse correlation to the incidence of poor diets. The fact is evidence of the strongest kind for the validity of considering these lesions to be signs or stigmas of inadequate nutrition. No one of them is

sufficiently specific to be conclusive evidence of nutritional deficiency and therefore none of them alone is diagnostic when applied to the examination of an individual. Applied to patients in a hospital, no one of them is very helpful as a measure of the adequacy of the diet, because among the sick many other abnormalities may affect nutrition. Applied, however, to groups or samples of a "nonsick" population, they do have meaning as an index of the adequacy of the diet. This may be accepted as a conclusion.

The incidence of several of the lesions mentioned was low in rural Wabasha County and very low in urban Rochester. However, the finding of an incidence for folliculosis, cheilosis and gingivitis of 20 to 25 per cent in Wabasha County and 10 per cent in Rochester, with poor musculature noted in approximately the same percentage of these children, leaves little ground for complacency about the adequacy of the diets of many of our Minnesota children; for such lesions, although relatively harmless in themselves, are accompanied not uncommonly, in Minnesota as in Newfoundland, by depression of the vigor of the mind and body, which represents depression of the quality of life.

It is not to be inferred from these conclusions that the problem can be solved by administering synthetic vitamins. Such products have a place in therapeutics. They also may be used with great advantage to improve the quality of certain foods, notably white bread. The great need, however, is for improving eating habits, which implies more emphasis on protective foods, adequate consumption of milk, eggs, meat, green and yellow vegetables, tomatoes and citrus fruits. The most effective way to accomplish such improvement is with school meals. The food habits of adults are fixed and difficult to change, and the results obtained by adult education have been discouraging. Unfortunately, the school lunch program is progressing much too slowly. In many schools no meals are served, and in schools where school lunches are established, the food selection is not always what it ought to be. If the school meal could provide not less than half the recommended allowances of protein, calcium, iron and the vitamins as a supplement to what the child obtained at home, and if the serving of each meal were made an occasion for demonstrating good food selection, we would witness very soon the end of malnutrition. For not only would the child be benefited, but the lesson and the habits formed would be carried to the homes these children soon will set up for themselves.

Discussion

Dr. E. F. Robb, Minneapolis: Children in Minnesota are probably more fortunate than children in any other state. Here, we do have an abundance of milk and eggs. It would be interesting to see how statistics on children in other parts of the country would compare with the statistics Dr. Wilder has given us tonight.

We all know that our boys are much larger than we are, and for this there may be an explanation. Many of us had little milk, oranges, et cetera, as youngsters. Oranges were largely a special treat at Christmas time.

Last fall a number of pediatricians were here from all over the world and I had an interesting conversation with one from Holland. He is the father of three children, and he stated that during the German occupation of Holland his children remained quite well, although they did not grow to any appreciable extent. He felt that since they had an ample supply of synthetic vitamins, their health had remained good, even though their caloric intake was insufficient to promote growth. There is no doubt that we would need fewer synthetic vitamins if we could be sure that everyone had proper diets. Since this is a very difficult goal to attain, it seems wise to continue the use of the various vitamin products that are commonly used.

I would like to have Dr. Wilder tell us a bit more about the cases he saw with bleeding gums. It is my impression that large doses of vitamin C are very helpful in cases of stomatitis and gingivitis. His observations on dental caries are also of great interest and may force us to change our ideas concerning this condition. All in all, I am sure that Dr. Wilder has given us a great deal to think about and that all of us have enjoyed this paper very much indeed.

Dr. R. T. La Vake, Minneapolis: Were any of these children put on vitamins and did you see any change in their condition?

Dr. S. Marx White, Minneapolis: I would like to know whether Dr. Wilder has any information or data he could supplement this with, as to our modern processing of foods—freezing, storage and canning—and whether such processing is known to play any part in deficiencies such as our own in Minnesota?

Dr. J. A. Lepak, St. Paul: Dr. Wilder has given us an excellent description of the lesions caused by vitamin deficiencies. The indiscriminate prescription of vitamins is unwise, I suppose, not only because it largely exploits the public and enriches those who produce them, but also because they may produce deleterious effects if taken in excessive dosage. I would like to ask Dr. Wilder if he has any data on hand to show the effects of overdosage in vitamins A and D, riboflavin, thiamine hydrochloride, niacin, et cetera? What would be the ill-effects of giving too large doses of one or more of these vitamins?

Dr. Vernon L. Hart, Minneapolis: I would like to know if the brownish transverse bands that seemed to be so common on the teeth were of any significance?

Dr. Henry L. Taylor, Minneapolis: I would like to know how these lusterless eyeballs differ from those in our malnourished population?

Dr. Wilder, in closing: I deplore as much as anyone the current indiscriminate use of pharmaceutical vitamins. I likewise deplore the fact that the active interest in nutrition occasioned by the war provided ammunition to exploiters of the vitamins. The bad accompanies the good always; nevertheless, to aim dietetically at the recommended allowances of the Food and Nutrition Board is certainly justifiable.

None of the children of the groups investigated were treated with pharmaceutical vitamins. However, in Newfoundland, by government regulation, all white flour imported was to be enriched, beginning about the time of our departure. This has resulted in a considerable increase in the intake of riboflavin, thiamine and niacin. We hope to visit Newfoundland again next year to observe the effects of this on the incidence of those tissue lesions commonly attributed to an inadequate intake of any of these vitamins. Nothing will have been done about the supply of vitamin C, and if we observe improvement of lips, tongue or conjunctiva and no change in the incidence of lesions of the gums, the improvement with reasonable assurance can be credited to the enrichment of the flour.

In line with this are observations of Jolliffe at the Bellevue Hospital in New York City. There, since enrichment of white bread and white flour was introduced, the incidence of lesions attributed to deficiency of riboflavin and niacin has markedly diminished. Also polyneuritis, which formerly was very common on the wards for alcoholics, has almost disappeared. That this improvement is related to enrichment of the bread and not to the increased purchasing power occasioned by the war is evidenced by the fact that the incidence of lesions attributed to inadequate intake of vitamin C has not decreased.

The Minnesota children were not put on vitamins, but from Florida comes a recent report of a similar study with observation of striking benefit from the institution of a satisfactory school lunch program which was supplemented for the first year with synthetic vitamins. The vitamins were given to those who appeared to be in need of them. That is, they were used as therapeutic agents, to which use one cannot take exception.

The question was asked whether various commercial practices for processing foods affect their vitamin contents. From what I have learned, as a member of the Council on Foods and Nutrition of the American Medical Association, the answer is that modern methods of canning do a very good job of preserving the vitamins and minerals of foods. Even the highly perishable vitamin C of citrus fruits is well preserved. With frozen foods there is little loss of anything. The principal vitamin loss occasioned by food processing resulted from the milling of wheat to make white flour. Enrichment of white flour has restored the content of thiamine, niacin and iron and has added riboflavin. It is to be hoped that enrichment of bread and flour can be made universal by legislation. Legislation also is desirable to assure the universal fortification of margarine with vitamin A and the universal fortification of table salt with iodine. No large section of the country is free from simple goiter, and such goiters are preventable with use of iodine. Recent surveys have revealed much adolescent goiter in regions which heretofore were considered to be goiterless.

Except in the case of vitamin D there is no good evidence of harm resulting from overdosage of any of the vitamins, and certainly there can be no danger of overdosage of vitamins from consuming food. Arctic explorers have developed ill-effects from eating the liver of polar bear which is said to be exceedingly rich in vitamin A, but few of us are likely to indulge excessively in polar bear liver.

There was little tooth brushing done in Newfoundland, which probably explains the brownish discoloration of some of the teeth shown in the lantern slides. I have no data on the fluoride content of the water in Newfoundland, but from the fact that the soil is very shallow and the underlying rock is largely igneous, I would guess its content of salts of all kinds to be low. I have heard that the fluoride contents of the drinking waters of Minnesota also are low. This may not be true, and before attributing the difference in the incidence of caries to the difference in the diets of Newfoundland and Minnesota, we ought to know about the fluoride of the waters used.

The lusterless ocular conjunctiva observed in Newfoundland was so much like that observed in the subjects of the experiment on semistarvation to which Dr. Taylor referred that when I saw those subjects I was led to suspect deficiency of vitamin A. The brownish pigmentation of the skin of the face observed in many of those subjects was also seen in Newfoundland, where the calories were sufficient but the supply of several vitamins was inadequate.

The meeting adjourned.

A. E. Cardle, M.D., *Secretary*

SILLIMAN'S VISIT TO MINNESOTA

(Continued from Page 293)

The Falls are of very inconsiderable elevation; it appeared to us about 20 feet—Dr. Owen writes 16 feet (Owens survey)—probably the height may vary with different stages of the water. It has but a very faint resemblance to Niagara where the water falls 150 feet on the British side and 164 on the American. Still the effect is grand. As at Niagara, the river is divided by an island, forming two branches, but united into one flood both above and below.

Above the island, the river at a medium stage of the water, as at the time of our visit, is fordable by horses and carriages and some people of our party crossed in that way. We regretted that we had not known that fording was practicable as it would have saved us a perilous passage on foot over a miserable apology for a bridge—a series of planks of no great width or strength, very imperfectly secured at the contiguous ends tempted us to pass as many others had done. There was no hand rail, except that for a short distance there was a dangerous substitute in a few narrow slips of boards imperfectly secured by nails. The violent rush of the torrent beneath the planks was in some places terrific and might cause some persons who have not steady nerves to become dizzy and fall. I led Sarah [his wife] with a firm grasp of a strong hand—but on our return she became faint and dizzy. I begged her to look up and not at the water; still I was very anxious and was relieved when Governor ? of one of the western states, a gentleman of noble person and bearing, took the lady's spare hand and we were soon safe over the flood, much to our relief. A suspension bridge now renders the passage safe. . . . We had to regret that we were not aware that we were in the near vicinity of the little cataract [Minnehaha Falls] called by the Aborigines the laughing water and which gave origin to Longfellow's pleasant poem of Hiawatha so remarkable for the skilful interweaving of Indian names into harmonious verses.

—Remarks by John F. Fulton, M.D., Sterling Professor of Physiology, Yale University School of Medicine, in address before the Ramsey County Medical Society, September 23, 1947.

Reports and Announcements

INTERNATIONAL POLIOMYELITIS CONFERENCE

The first International Poliomyelitis Conference, to be held at the Waldorf Astoria Hotel in New York, July 12 to 17, has been called by the National Foundation for infantile Paralysis, with the co-operation of numerous national scientific organizations and government agencies. Addresses by leading world authorities on poliomyelitis will cover all phases of the subject, including research and treatment. The purpose of the conference will be to pool world knowledge about the disease and to expedite distribution of this knowledge on a world-wide basis.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The National Gastroenterological Association will hold its thirteenth scientific session at the Hotel Pennsylvania in New York City, June 7-10, 1948.

In response to popular request, the program this year will again for the most part consist of symposia, and there will be one panel discussion.

The program for the first three days will be at the Hotel Pennsylvania and will consist of symposia on gastroduodenal ulcer; ulcerative colitis; jaundice and metabolism, nutrition and allergy. The panel discussion, which will be followed by a "question and answer" period, will cover the topics of diabetic, tubercular, psychosomatic and cardiac manifestations in gastrointestinal diseases.

The fourth day of the session will be devoted to a clinical day at co-operating hospitals in New York City.

At the annual banquet to be held on Tuesday evening, June 8, the winner of the National Gastroenterological Association's 1948 cash prize award contest for the best unpublished contribution on gastroenterology or an allied subject, will receive the prize of $100.00 and a certificate of merit.

Further details and a copy of the program may be obtained by writing to the Secretary, National Gastroenterological Association, 1819 Broadway, New York 23, New York.

SOCIETY OF AMERICAN BACTERIOLOGISTS

The annual meeting of the Society of American Bacteriologists will be held in Minneapolis May 10 through 14, with headquarters at the Nicollet Hotel. Among other sessions, there will be those on medical bacteriology, immunology and comparative pathology.

E. STARR JUDD LECTURE

The fifteenth E. Starr Judd lecture will be given by Dr. Alfred W. Adson, professor of neurosurgery at the Mayo Foundation, on April 29 at 8:15 p.m. in the auditorium of the University of Minnesota Museum of Natural History. Dr. Adson's subject will be "The Evolution of Neurosurgery."

The late Dr. E. Starr Judd, an alumnus of the University of Minnesota Medical School, established this annual lectureship in surgery a few years before his death.

MINNESOTA DIVISION AMERICAN CANCER SOCIETY

Dr. Arthur H. Wells, head of the Department of Pathology, St. Luke's Hospital, Duluth, was elected president of the Minnesota Division of the American Cancer Society at a meeting of the board of directors in Saint Paul on February 11. Dr. Wells succeeds the late Dr. William A. O'Brien, who had been president of the society for eight years at the time of his death in December.

Among other officers named by the board of directors was Dr. John J. Bittner, of the University of Minnesota, who was elected second vice president.

HENNEPIN COUNTY SOCIETY

Recently elected president of the Hennepin County Medical Society is Dr. Edward Dyer Anderson, Minneapolis, who will take office in October, succeeding Dr. Ralph H. Creighton.

Other officers of the society will be Dr. Robert F. McGandy and Dr. Karl W. Anderson, first and second vice presidents, respectively. Newly elected as board members are Dr. Russell W. Morse and Dr. Leo G. Rigler, board of directors; Dr. James A. Johnson and Dr. Erling S. Platou, board of censors; Dr. George N. Aagaard and Dr. Chauncey A. McKinlay, board of ethics, and Dr. Thomas J. Kinsella and Dr. T. A. Peppard, board of trustees. Named as delegates to the state association are Dr. Kinsella, Dr. Claude J. Ehrenberg, Dr. Douglas P. Head, Dr. Reuben A. Johnson, and Dr. Walter H. Ude.

WASECA COUNTY SOCIETY

At the annual meeting of the Waseca County Medical Society, held in Waseca early in January, Dr. R. C. Hottinger, Janesville, was elected to the office of president to succeed Dr. G. H. Olds, new Richland.

Also elected was Dr. S. C. G. Oeljen, Waseca, vice president, succeeding Dr. J. M. McIntire, Waseca, while Dr. C. T. Wald, Janesville, was named to replace Dr. Oeljen as secretary-treasurer.

The need for expansion of the Waseca Memorial Hospital was discussed, and use of a mobile x-ray unit for a country-wide survey was approved.

WASHINGTON COUNTY SOCIETY

At the January meeting of the Washington County Medical Society, held in Stillwater on January 13, Dr. Robert W. Holmen, Saint Paul, was the principal speaker, discussing the subject, "Allergy."

When the society met in Stillwater on February 10, Dr. Karl H. Pfuetze, of Mineral Springs Sanatorium, demonstrated the reading of eighty-two chest x-ray films taken of Stillwater high school students on November 4, 1947.

"The most satisfactory results . . ."

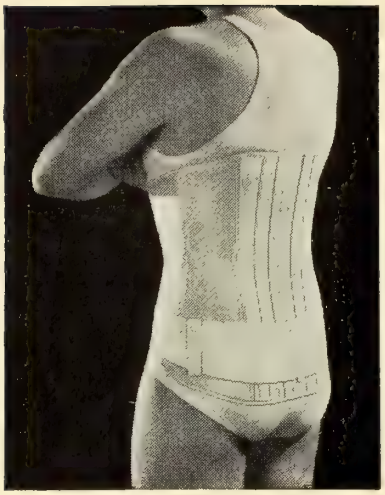
IRRITABLE BOWEL SYNDROME

"Therapeutic efforts toward the relief of constipation in patients with an irritable bowel syndrome must be continued over prolonged periods of time. Cathartics which exert their action by direct irrigation of the intestinal mucosa have no place in long-term bowel management. . . . The most satisfactory results were obtained with a hydrophilic mucilloid [Metamucil] prepared from psyllium seed. . . ."*

METAMUCIL

When prolonged treatment is indicated, Metamucil—the "smoothage" management of constipation—fits well into the program.

Smooth, gentle, normal evacuation—the desired action in the irritable bowel syndrome—is afforded by the use of Metamucil.



ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

Metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent. Metamucil is the registered trademark of G. D. Searle & Co., Chicago 80, Illinois.

SEARLE

RESEARCH IN THE SERVICE OF MEDICINE

a SPENCER for intervertebral disc

In both conservative and surgical treatment of intervertebral disc, the application of a back support is usually indicated.*

We invite the physician's investigation of Spencer as adjunct to treatment. Each Spencer is *individually designed, cut, and made* for each patient—after a description of the patient's body and posture has been recorded and detailed measurements taken. Thus, individual support requirements are accurately met. The Spencer Spinal Support shown above was individually designed for this man. Note outside pelvic binder for added pelvic stability.

For a dealer in Spencer Supports look in telephone book for "Spencer corsetiere" or "Spencer Support Shop," or write direct to us.

WOMAN'S AUXILIARY

Hennepin County

The Woman's Auxiliary to the Hennepin County Medical Society held its annual open meeting and health education program on Friday, March 5, 1948, at 1:30 p.m. in the auditorium of the Minneapolis Institute of Arts. Invitations were extended to representatives of women's clubs engaged in civic, philanthropic, health and educational work, and to the officers and committee chairmen of the Woman's Auxiliary to the Minnesota State Medical Association, as well as the county presidents. The speakers were graciously introduced to the members and their guests by Dr. Ralph H. Creighton, president of Hennepin County Medical Society. Dr. Richard R. Cranmer spoke on "Prepaid Medical Service," and Dr. H. N. Wright, Associate Professor of Pharmacology at the University of Minnesota, spoke on "New Drugs."

Following the lectures, tea was served in the upstairs galleries. Among the guests were Mrs. Julius Busher and Mrs. T. N. Fleming of St. Cloud, Mrs. J. L. Benepe, Mrs. H. H. Fesler and Mrs. Wm. Von der Weyer of Saint Paul and Mrs. Hobart M. Johnson of Mankato.

St. Louis County

Members of the Woman's Auxiliary to the St. Louis County Medical Society entertained their husbands at an annual dinner dance on Saturday evening, January 31, at the Kitchi Gammi Club, Duluth. Mrs. J. A. Thabes, State President, was a guest at the regular January meeting.

The February meeting of the Auxiliary was held February 10 at the Duluth Woman's Club. Luncheon was at 1 P.M. At this meeting Mrs. C. L. Thomas gave a review of "The Bishop's Mantle" by Agnes Turnbull.

Southwestern Minnesota

The Southwestern Medical Society, its Auxiliary and District Unit No. 5 of the Minnesota Department of Health sponsored an all-day "Health Day" at the Worthington Armory, Worthington, Monday, February 23. "Community Health Problems" was the subject of the morning session. Dr. Gaylord W. Anderson, Mayo professor and director of the School of Public Health, University of Minnesota, was the chairman. Participants were Mrs. J. S. Jones, Executive Secretary of the Minnesota Farm Bureau, and Mrs. Harold Wahlquist of Minneapolis, national Public Relations Chairman.

A panel discussion on "Home Safety" was conducted in the afternoon by Dr. Robt. N. Barr of the Minnesota Department of Health. "Safety on the Farm" was also discussed at this meeting. Dr. Dale B. Harris, acting director of the Institute of Child Welfare, University of Minnesota, conducted a panel dealing with the "Behavior problems in children" and other aspects of mental health. Winners of a "Nutrition and Farm and Home Safety" poster contest were introduced in the evening. Governor Luther W. Youngdahl was the principal speaker of the evening. This "Health Day" is the first of its kind in Minnesota.

Some things you should know about **operations**

No. 210 in a series of messages from Parke, Davis & Co. on the importance of prompt and proper medical care.

OF ALL THE RECENT ADVANCES in medical science none have been more dramatic than those in surgery and the fields related to it. Take appendicitis, for instance.

Not very many years ago, having your appendix out might have meant a fairly long and uncomfortable hospital sojourn, followed by several tedious weeks of getting back your strength. And with it all you might have had good reason to fear such complications as peritonitis or pneumonia.

Nowadays, except for a few rare cases, the removal of an appendix is not considered a serious operation. And many operations which were considered of major seriousness as recently as 1930 are now often relatively simple.

Because of notable advances in training and surgical skill, many of the risks have been almost eliminated. Complications following operations are far less common. And most patients recover in a shorter time, and with less discomfort than formerly.

Such progress in surgery has been hastened by significant developments in four important fields.

1. Anesthesia. The administration of anesthetics has become a specialized science. New anesthetics have been developed—less toxic, less upsetting to respiration and heart action. With modern anesthesia the patient has a far easier time when undergoing surgery. Post-operative nausea and vomiting, which were previously almost taken for granted, are now much less frequent.

2. Infection-fighting drugs. Peritonitis, once feared as a frequent complication of abdominal surgery, today is uncommon. The use of such agents as the sulfa drugs and penicillin—to treat infection or to guard against it—has almost eliminated many of the infections which formerly constituted the greatest dangers in surgical procedures.

3. Early ambulation. Doctors have found that getting patients out of bed soon after operations not only speeds recovery, but also prevents many of the discomforts formerly suffered. Bowel and urinary functions are quickly restored. Gas pains are usually avoided. It is not unusual nowadays for a patient to be well enough to go home from the hospital in less than ten days after a major operation.

4. Body Nutrition. One of the problems in surgery has been that the condition which makes an operation necessary is usually one which has depleted the patient's nutritional reserves, and therefore lessens his ability to recover promptly from the operation itself.

In recent years, however, medical science has broadened its knowledge of body nutrition.

Today, it is possible to determine in what a patient's body is deficient—whether he needs whole blood, vitamins, salts, carbohydrates, protein.

Each of these elements can be replaced—making it far easier for the patient to go through an operation. Post-operatively, also, recovery is hastened by supplying the body's needs in easily assimilated form.

SEE YOUR DOCTOR. Give him your complete confidence at all times. If he advises an operation, follow his recommendation promptly. With modern surgery, with modern hospital care, you have little reason to be afraid.

Remember, too, that when surgery is indicated, a delay may be dangerous. Prompt action is likely to give you a quicker recovery—and an easier one!

In Memoriam

CHARLES P. ALING

Dr. Charles P. Aling, for more than forty years a member of the staff of St. Barnabas Hospital in Minneapolis, died January 16, 1948, at the age of sixty-nine.

Dr. Aling was born near Blue Earth, Minnesota, in 1878. He graduated from Rush Medical School in 1900 and practiced at Marine-on-St. Croix, for three years before locating in Minneapolis.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations.

Dr. Aling is survived by his wife, Genevieve; a daughter, Mrs. Adrian Kennison of Plainfield, New Jersey, and a son, Dr. Charles A. Aling of Minneapolis.

HERMAN A. FASSBENDER

Dr. Herman A. Fassbender, mayor of Hastings, Minnesota, died January 7, 1948, after a year's illness.

Dr. Fassbender was born in Hastings, January 20, 1894. He obtained his medical degree from the University of Minnesota in 1920 and for the past eighteen years has maintained St. Raphael's hospital in Hastings. He was a councilman for four years and mayor for the two-year terms of 1935-1936, 1940-1941 and 1946-1947.

Dr. Fassbender is survived by his wife, three sons, Dr. William of Alma, Wisconsin, Dr. Herman T. at St. Louis University and David of Hastings and two daughters, Mary Margaret and Eileen.

FRED WILLIAM GAARDE

Dr. Fred W. Gaarde, since 1920 an internist in the Mayo Clinic, died February 10, 1948, following a long illness.

Dr. Gaarde was born June 20, 1887, at Minden, Nebraska. He obtained a B.S. degree from the University of Chicago in 1909 and his M.D. from Rush Medical School in 1912. Interning first at the Akron City Hospital for six months, he spent the following eighteen months at the Presbyterian Hospital in Chicago. He then became associated with Dr. Frank Billings in Chicago and practiced there from 1913 until he entered the army in 1918. After serving overseas, he was discharged as a major in 1926.

In 1920, Dr. Gaarde became connected with the Mayo Clinic, becoming head of a section in medicine in 1926. At the time of his death, he was a Senior Consultant in Medicine and Assistant Professor of Medicine at the Mayo Foundation.

He was a fellow of the American College of Physicians, a member of the Chicago Society of Internal Medicine, the Central Society for Chemical Research, the Minnesota Society of Internal Medicine, the Olmsted-Houston-Fillmore County Medical Society and the Minnesota State and American Medical Associations.

On May 20, 1915, Dr. Gaarde married Hazel Holman. She and two sons, Dr. Fred Gaarde, Jr., of Rochester and Richard Gaarde, who is with the Naval Air Corps in Trinidad, his mother, Mrs. Anna Klith Gaarde and a brother John of Hastings, Nebraska, survive him.

VERNER G. HESELTINE

Dr. Verner G. Heseltine, well-known physician of Taylors Falls, Minnesota, passed away December 8, 1947. He was seventy-two years old.

A native of Australia, Dr. Heseltine was born in Adelaide, South Australia. He went to England at the age of nineteen and graduated from St. Bartholomew's Hospital Medical School. He practiced at the Rotunda Hospital, Dublin, before coming to Taylors Falls thirty years ago.

Dr. Heseltine had been a member of the Ramsey, Chicago-Pine and East Central County Medical Societies, the Minnesota State and American Medical Associations. He was also a member of the Royal College of Surgeons.

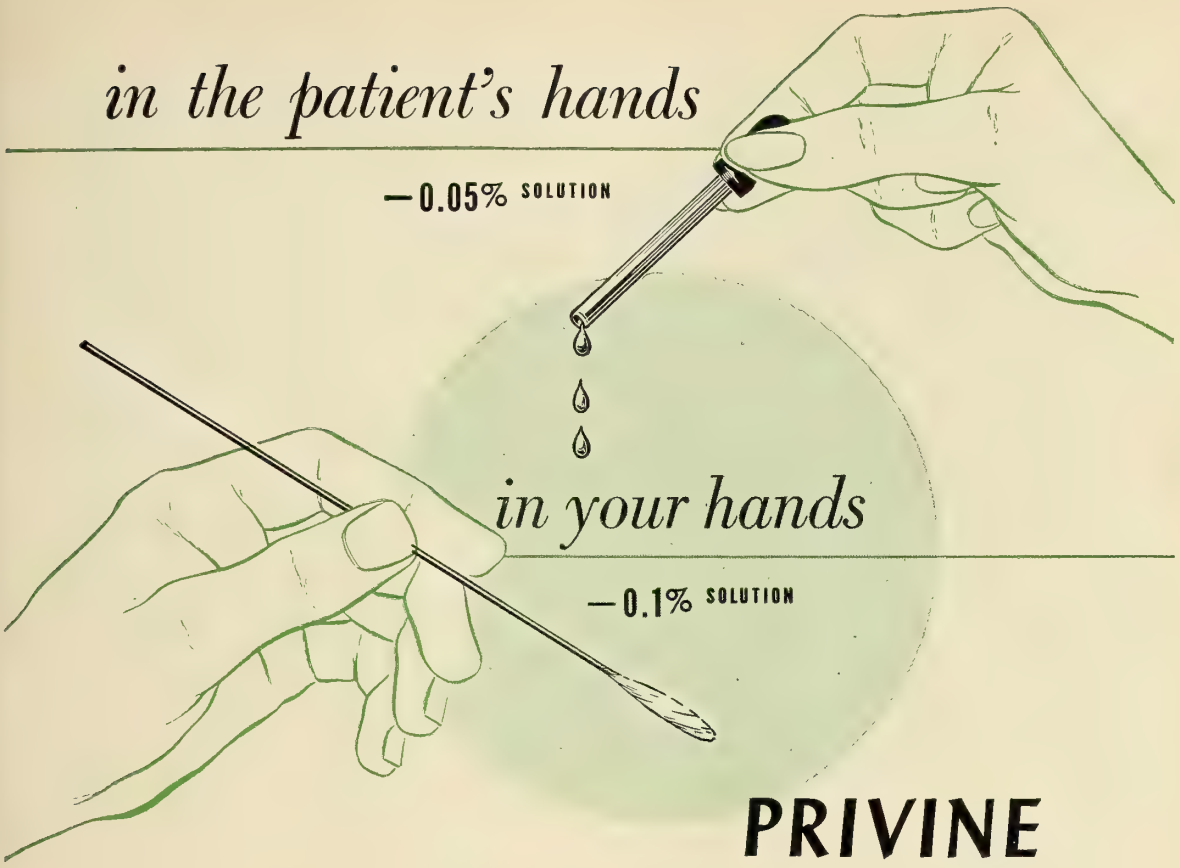
Dr. Heseltine's wife, the former Jessica O'Brien, died four years ago. He is survived by two daughters, Mrs. Kenneth Pepper and Mrs. Ben Bezina of Taylors Falls, and two brothers who live in Australia.

PAUL HAROLD KELLY

Dr. Paul H. Kelly, well known as a surgeon in Saint Paul for the past thirty-six years, died suddenly at the age of sixty-three at St. Josph's Hospital on January 9, 1948.

The youngest of eight children, Dr. Kelly was born on October 5, 1884, the son of the late Daniel W. Kelly and Mary Collins Kelly. By a strange coincidence his death took place in the same hospital in which he was born.

He attended the Saint Paul grade schools, Cretin and Central High Schools and Hamline University for a year. He received a degree as pharmaceutical chemist in 1904 and his M.D. in 1911, both from the University of Minnesota. During the later years of his medical training, he lived at St. Joseph's Hospital in the capacity of an extern. During this time, he also acted when called upon as relief for the police surgeon at night.



After graduation in 1911, Dr. Kelly interned at Ancker Hospital, then known as the City and County Hospital in Saint Paul, was city physician from 1912 to 1914, and a member of the surgical staff of Ancker Hospital from 1912 to 1928. He was also a member of the staffs of St. Joseph's, Miller, St. Lukes, Midway and St. John's Hospital. He was a member of the advisory board of St. Joseph's Hospital from 1934 to 1939 and the chief of staff in 1939.

Dr. Kelly was a member of the Ramsey County Medi-

PRIVINE

PRIVINE hydrochloride, 0.05 per cent, is sufficiently potent to produce long-lasting relief in the average case of nasal congestion in patients of all ages. It is therefore the Privine preparation of choice for regular prescription purposes.

Privine hydrochloride, 0.1 per cent, fills the need for an agent which will produce the intense vasoconstriction frequently necessary for adequate visualization and for pre- and post-operative shrinkage. It is therefore the Privine preparation of choice for direct use in the office or hospital.

When properly administered, Privine hydrochloride induces prolonged vasoconstriction with relative freedom from local or general side effects. Three drops will usually produce nasal decongestion lasting 3–6 hours. Overdosage should be avoided.

Issued: 0.05%, bottles of 1 fl. oz. and 16 fl. ozs. • Jelly, 0.05%, tubes of 20 Gm.
0.1%, bottles of 16 fl. ozs. only

PAUL HAROLD KELLY

(Continued from Page 310)

cal Society, the Minnesota State and American Medical Associations, a Fellow of the American College of Surgeons and a member of the American Association of Railroad Surgeons. In recent years, he was local surgeon for the Chicago, Milwaukee and Saint Paul and the Chicago, Great Western railways.

Dr. Kelly was one of the first surgeons in Saint Paul to specialize in industrial surgery, and as a result of his experience, his advice and counsel were frequently sought. He published several articles in MINNESOTA MEDICINE: one in 1922 entitled "Strangulated Hernia—Report of Cases"; his part in a Symposium on Emergency Surgery held at the 1933 meeting of the Minnesota State Medical Association, and in 1934 an article entitled "Industrial Accidents—A Report of 2,000 Cases."

Dr. Kelly was a member of the Alpha Kappa Kappa medical fraternity and a life member of the Saint Paul Athletic Club. Hunting was his favorite hobby. He possessed a fine tenor voice and enjoyed classical music in all its forms.

Dr. Kelly was married in 1914 to Leslie F. Terry of Saint Paul. She preceded him in death in February, 1945. Surviving him are four children: Paul Richard of Modesto, California; Howard William of Balboa Island, California; Dr. William Daniel, captain in the Army Medical Corps now in Japan; and Elizabeth Louise (Mrs. Jack C. Cooper) of Milwaukie, Oregon. He is also survived by his brother, Dr. John V. Kelly, and sister, Miss Margaret E. Kelly, both of Saint Paul.

KARL DEDOLPH

CLARENCE GEORGE PERRY

Clarence George Perry passed away suddenly January 6, 1948, at McAllen, Texas. He was born in Saint Paul, Minnesota, July 27, 1885, the son of A. W. and Mary Josephine Perry. He graduated from Humboldt High School, and the University of Minnesota Medical School in 1909, after which he served as intern at the City and County Hospital in Saint Paul. Following his internship he took postgraduate work in New York City. Returning to his native city he engaged in general practice with the late Dr. Michael Welch on the West Side.

Following his discharge from the Army, in which he served as a captain during World War I, he engaged in the study of his chosen specialty, eye, ear, nose and throat, in Bellevue Hospital in New York City. On his return to Saint Paul, he became associated with Dr. Henry Beaudoux with offices in the Lowry Building. When Dr. Beaudoux left the city, Dr. Perry continued his practice alone until his retirement January 1, 1947.

He was a member of the Saint Paul Athletic Club, the Town and Country Club, serving as president of the latter in 1935. He was also a member of Nu Sigma Nu Fraternity, Ramsey County Medical Society, Minnesota State Medical Association, and the American Medical Association.

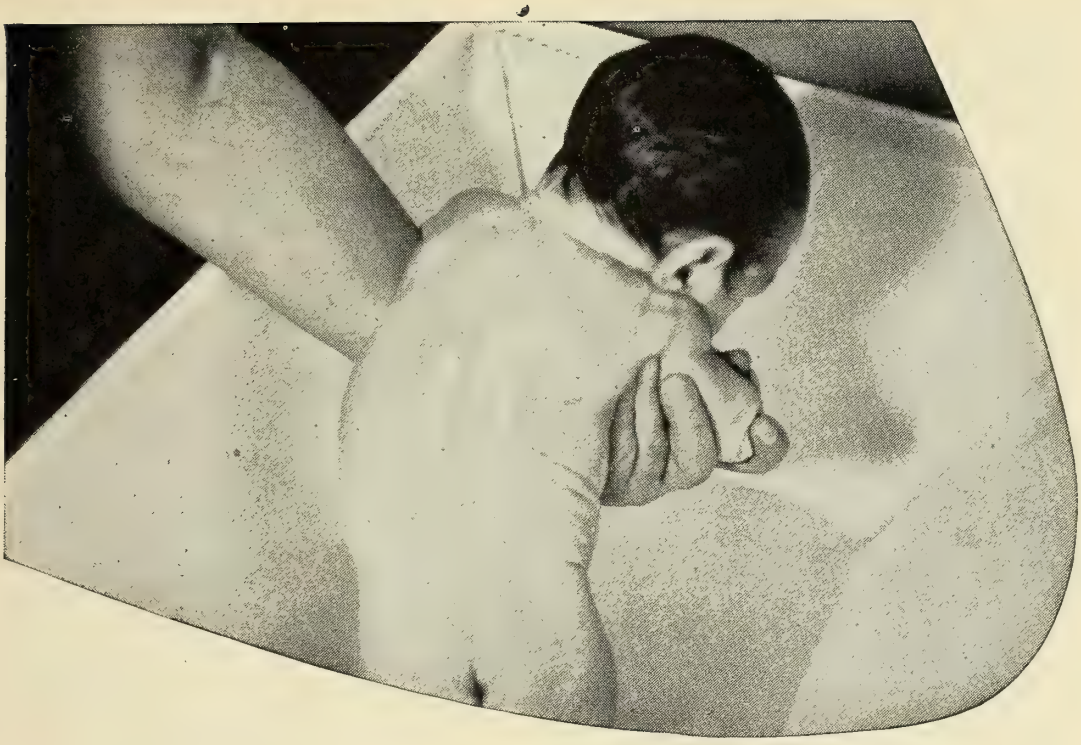
Clarence's hobbies were golf, hunting and fishing, and he was most proficient in all.

He was married to Maude Gould on May 30, 1914. Surviving are his wife, a sister, Mrs. Fred Hennessy, two nieces and two nephews.

His gracious personality, his kindly smile, and pleasant ways endeared him to a host of friends. He will be missed by many people, in many ways.

CARL L. LARSEN, M.D.

CARDIAC EMERGENCIES



(Continued from Page 263)

and treat cardiac diseases should have ample knowledge to diagnose cardiac emergencies correctly and to know the correct procedures of treatment.

2. One must use common medical sense in many of these cases. Digitalis preparations are not to be used in every cardiac patient. Probably one reason why many patients have not died because of the abuse of digitalis is because the attending physician has not digitalized the patient. The electrocardiogram is not necessary at once in all cases, since it may needlessly aggravate the condition which is already present. This is true of many laboratory procedures. Make the diagnosis, treat the patient, then establish the diagnosis by laboratory means if necessary.

First breath, first bath, first bottle

In a life filled with "firsts", baby has no time to cope with such gastro-intestinal problems as carbohydrate fermentation and attendant distention and diarrhea—particularly during his first few weeks.

'Dexin' has proven an excellent "first carbohydrate" because 1) its high dextrin content is not fermentable by the organisms usually present in the intestinal tract, and 2) because it promotes the formation of soft, flocculent, easily digested curds.

Simply prepared in hot or cold milk, 'Dexin' brand High Dextrin Carbohydrate is easily adapted to increasing formula needs from month to month, and later, being palatable but not too sweet, is a welcome supplement to other bland foods. 'Dexin' *does* make a difference.

'Dexin' HIGH DEXTRIN CARBOHYDRATE
BRAND

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

Crystalline Penicillin G Sodium Merck is now supplied in vials with a new, improved aluminum seal.

Among the advantages provided by this new seal are:

- The round tear-off tab is easily removable and eliminates the necessity of using a knife or other implement to pry up the tab.
- The tight-fitting dust cap with skirt provides protection for the rubber stopper during storage of the vial between injections.

Crystalline Penicillin G Sodium Merck is a highly purified product from which therapeutically inert materials have been virtually eliminated.

For medically sound reduction of overweight...

Benzedrine Sulfate—rational and accepted

BENZEDRINE SULFATE, by safely depressing the overweight patient's appetite, ordinarily curbs excessive eating. Lowered caloric intake and loss of weight naturally follow. Hence, Benzedrine Sulfate therapy is medically sound and highly effective.

Thyroid—irrational, potentially dangerous and widely condemned

In overweight, most authorities strongly condemn thyroid therapy as irrational and potentially dangerous, except in those rare instances when an accompanying hypothyroidism has been definitely demonstrated.

BENZEDRINE SULFATE—unlike thyroid—ordinarily, in the proper dosage, has no significant effect on the basal metabolic rate, blood pressure, or heart rate. Harris, Ivy and Searle,[1] after a comprehensive series of functional tests, conclude: "No evidence of deleterious effects of the drug (amphetamine sulfate) was observed."

[1]Harris, S. C.; Ivy, A. C., and Searle, L. M.: THE MECHANISM OF AMPHETAMINE-INDUCED LOSS OF WEIGHT: A Consideration of the Theory of Hunger and Appetite, J.A.M.A. 134:1468 (Aug. 23) 1947.

Benzedrine* Sulfate

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address:
Registrar, 427 S. Honore St., Chicago 12, Ill.

Two Mayo Clinic physicians spoke at the Careers Day conference held at Carleton College, Northfield, on February 11. Dr. Arthur B. Hunt, consultant in obstetrics and gynecology at the clinic, discussed the field of medicine, and Dr. A. H. Sanford, senior consultant in the division of clinical laboratories, told students at Carleton about medical technology. Thirty-four business and professional men and women participated in the conference which was designed to assist students in choosing a life work.

* * *

Now on the staff of the Gamble Clinic in Albert Lea is Dr. O. A. Erdal, formerly of Milwaukee, Wisconsin, who joined the group late in January.

A native of Bricelyn, Dr. Erdal graduated from the University of Minnesota Medical School in 1943, serving his internship at St. Mary's Hospital in Milwaukee. After a period as a flight surgeon in the Air Forces, he returned to St. Mary's Hospital where he served as chief resident for a year and a half.

* * *

Principal speaker at a meeting of Section One of the Child Psychology Study Circle, held in Saint Paul on February 2, was Dr. Edward Dyer Anderson, clinical associate professor of pediatrics at the University of Minnesota, who spoke on "The Art and Wisdom of Being a Parent."

A native of Duluth who studied medicine at the University of Minnesota, later taking postgraduate work at Harvard and in Vienna, Dr. Anderson served in World War II as a captain in the navy medical corps.

* * *

Included in the group of Minnesota physicians who attended a continuation course in proctology at the University of Minnesota February 2 to 7 were Dr. C. A. Saffert, New Ulm; Dr. James L. Turner, Rochester; Dr. Philip F. Eckman, Duluth, and Dr. Marshall I. Howard and Dr. Norman F. Stone, both of Mankato. The course was given under the direction of Dr. Walter A. Fansler, clinical assistant professor of surgery, and consisted of lectures at the Center for Continuation Study and clinics at Minneapolis General and Fort Snelling Veterans Hospitals.

* * *

Establishment of a social security health program, assuring adequate medical and hospital care for all persons with low incomes, was recommended by Governor Luther W. Youngdahl in a talk at the annual convention of the Minnesota Federation of County Fairs on January 22 in Minneapolis.

In speaking of health programs in Scandinavian countries which he recently visited, Governor Youngdahl said, "We have got to come to something of that kind. We must make sure very citizen of the lower income group is provided with decent hospital and medical care."

The attenion of the profession is again called to the service given by the cancer home known as Our Lady of Good Council, located at 2076 St. Anthony Avenue, Saint Paul. The home was established in 1941 and is

More Natural Vision . . . with MAY-O-LITE

Low Reflection Lens Coating is an inexpensive treatment that increases the efficiency and comfort of lenses.

Low Reflection Lens Coating reduces surface reflection 75 to 90%; helps harden the lens against surface scratches; renders the glasses less conspicuous, more natural-looking.

You, as a refractionist, can instantly realize what this means to wearers of glasses.

It diminishes eye-strain. It means more natural comfort and vision for your patients.

This new process, developed during the war as a means to improve image definition in military instruments, reduces surface reflection, yet increases transmission of light—and eliminates out-of-focus "ghost images."

Write for a descriptive pamphlet and a treated sample of glass today. Then explain Low Reflection Lens Coating to your patients. It is available through most manufacturing and dispensing opticians.

MAY RESEARCH
126 South Third Street

operated by the Sisters of the Third Order of Saint Dominic of the Catholic Church for indigent and incurable cancer patients, irrespective of their color or creed. All that is necessary for admission is a letter from the patient's physician giving the diagnosis, the medications being used, a brief history and a statement of incurability and indigency. No money is accepted for the care of any patients admitted, but contributions to the home are accepted.

* * *

Two educational talks on cancer control were presented before Duluth groups on February 10.

Dr. Elizabeth Bagley, Duluth, spoke at a meeting of the Duluth Business and Professional Women's Club at the Arrowhead Hotel, presenting a motion picture on cancer entitled "The Traitor Within." Members of the B'nai B'rith Lodge, at a meeting in Temple Emanuel, heard an address by Dr. C. H. Mead, Duluth, and saw a moton picture on cancer control entitled "You Are the Switchman."

Both talks were scheduled through the speakers' bureau of the Duluth District of the American Cancer Society.

Two new physicians became associated with the Mesaba Clinic on January 19. Joining the group at the Hibbing clinic was Dr. W. H. Ylitalo, while Dr. R. C. Fortier became a member of the clinic at Marble and Calumet.

Dr. Ylitalo, a former resident of Keewatin, graduated from the University of Minnesota and interned at the Mare Island Naval Hospital in California. Dr. Fortier, formerly of Little Falls, also graduated from the University of Minnesota Medical School but served his internship at Minneapolis General Hospital. Both physicians are engaging in general practice.

"Facts and Figures about Infantile Paralysis," (1948 edition), a publication of the National Foundation for Infantile Paralysis, is now available to physicians and public health workers. Incidence of the disease in the United States is shown in tables, maps and charts. Statistics furnish information on age and sex distribution, case rates, crippling conditions and mortality. For the first time, the publication includes data on the disease in foreign countries.

Copies of the booklet (No. 59) may be secured free of charge from the Education Service, National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y.

A roundtable discussion on cancer concluded the annual meeting on January 20 of the Minnesota Division of the American Cancer Society, held in the auditorium of the University of Minnesota Museum of Natural History.

Speakers at the discussion, which was open to the public, were Dr. Arthur H. Wells, Duluth, president of the division and chairman of the roundtable talk; Dr. Henry Michelson, head of the Department of Dermatology at the University; Dr. R. S. Ylvisaker, clinical associate professor of internal medicine; Dr. Maynard Nelson, clinical instructor of surgery; Dr. Dean Fleming, chief of the preventable disease section of the Minnesota Department of Health, and Dr. J. C. Erhrenberg, Minneapolis gynecologist.

* * *

Inducted as president of the American Academy of Orthopaedic Surgeons on January 28, at its annual meeting in Chicago, Dr. Myron O. Henry of Minneapolis stated that orthopedic surgery is making "fabulous" strides. Citing statistics to show the need for this type of survery, he said that (1) about 1,150,000 persons were hurt in auto accidents in 1947, many suffering complicated bone and joint injuries; (2) disabling accidents occurred to 10,400,000 persons in 1946, with 370,000 of them becoming permanently disabled, and (3) at least 6,850,000 Americans now have rheumatism or arthritis, and 2,600,000 more have specific orthopedic faults.

A graduate of the University of Minnesota in 1920, Dr. Henry is a staff member of Northwestern Hospital, Minneapolis, and a clinical assistant professor of surgery at the University of Minnesota.

* * *

New cement building blocks, designed to reduce dampness in low-cost homes, have been developed by Dr. H. R. Tregilgas, Saint Paul.

When he discovered that many of his patients with pulmonary diseases were living in damp basement houses, the Saint Paul physician decided that prevention might be better than cure. Looking for some means of reducing dampness in cement building blocks, he found a way of sandwiching an asphalt insulation board between two concrete sections held together with galvanized reinforcing wire.

Tests conducted at the University of Minnesota Institute of Technology have shown that the new blocks increase insulating efficiency about 40 per cent. At the present, temperature and moisture tests are being conducted in a five-room house which was recently constructed of the new blocks in South Saint Paul.

Southwestern Minnesota Health Day, the first occasion of its kind in Minnesota, was held in Worthington on February 23. Participating in the all-day meeting were representatives from Pipestone, Murray, Cottonwood, Rock, Nobles and Jackson counties.

Panel discussions on community health problems, home and farm safety, and child behavior problems were included in the program prepared by local public health workers and representatives of the Minnesota Department of Health. Also shown during the day were several motion pictures on home safety, nutrition, dental health and similar subjects. At the evening meeting, the six winners of a health and safety poster contest, which had been held in the high schools of the six counties, were introduced. Principal speaker of the evening was Governor Luther W. Youngdahl. Among physicians participating in the health day were Dr. B. O. Mork, Jr., Worthington, and Dr. Robert N. Barr of the Minnesota Department of Health.

* * *

Dr. George N. Aagaard, Minneapolis, has been appointed by the Board of Regents of the University of Minnesota to succeed the late Dr. William A. O'Brien as director of postgraduate medical education at the University.

A graduate of the University of Minnesota Medical School in 1937, Dr. Aagaard interned at the St. Cloud Hospital and at Minneapolis General Hospital. In 1942, following four years of general practice in Minneapolis, he was appointed to a medical fellowship at the University, and in 1943 he was named a clinical instructor in medicine. With his appointment to admitting physician in the Division of Internal Medicine in 1946, he was promoted to the rank of assistant professor.

Last year, Dr. Aagaard re-entered the private practice of medicine in Minneapolis, but retained a clinical professorship in medicine at the University. His new appointment as director of postgraduate medical education, which became effective March 1, carries the rank of associate professor of medicine.

The first cure of rhinoscleroma by streptomycin has been announced.

Reported recently in the *Proceedings of the Staff Meetings of the Mayo Clinic,* the successful nonsurgical treatment of the rare nose disease was described by Dr. Kenneth D. Devine, Dr. Lyle A. Weed, Dr. Donald R. Nichols and Dr. Gordon B. New of the Mayo Clinic.

While considering performing a tracheotomy on a patient with rhinoscleroma, the physicians discovered bacteria of the Klebsiella family in one of the hard masses of tissue that had grown down into the larynx. Accordingly, it was decided to try streptomycin therapy. After one week of streptomycin injections, it became necessary to halt treatment because of the development of side reactions. Twelve days later, the streptomycin injections were resumed and then continued for forty-three consecutive days. After receiving 95 grams of streptomycin within a period of two months,

At a special meeting of the Park Region Medical Society in Fergus Falls on January 16, representatives of the Minnesota Department of Health explained the functions and purposes of a unit of the state department that was to be established in the city to take care of twelve counties in that part of the state.

Introduced by Dr. W. L. Burnap, Fergus Falls, were Dr. Robert N. Barr, Dr. Percy T. Watson, and Miss Nora Rolf, field nurse, all of the State Department of Health. The three speakers pointed out that the new unit would be similar to five already set up throughout the state—at Duluth, Bemidji, Rochester, Worthington and Mankato—and that plans were to add three more units. They said that the unit at Fergus Falls would consist of a part-time physician, a sanitation engineer, a field nurse and a clerk, who would supervise county public health nurses, investigate sources of communicable disease, take part in health programs, and assist local physicians in preventing disease. The local unit would be a means of bringing the functions and aid of the Minnesota Department of Health more directly into the community.

* * *

The Cottonwood County Medical Club, of which Dr. Homer Basinger of Windom is secretary, has announced that vaccinations against smallpox and diphtheria were carried out on October 24 and November 21, 1947, in the six towns of Cottonwood Couny—Windom, Bingham Lake, Mt. Lake, Storden, Jeffers and Westbrook.

Immunization clinics were organized by the local physicians and the County Nursing Service in conjunction with the Minnesota Department of Health. Information was distributed to children in both rural and town schools, and newspapers carried advance information regarding the clinics. As a result, the following vaccinations were carried out: smallpox—1,097 (11 in children under one year of age, 133 in the one-to-four age group, and 953 in those five years or over); diphtheria—1,558 (22 in those under one year, 201 in the one-to-four age group, and 1,328 in those five years or over). In addition, 607 diphtheria booster inoculations were given (33 in the one-to-four group). The reason given for the low number vaccinated in the preschool age group is that it is estimated that 80 per cent of the children in this group had already been vaccinated before they were two years old.

* * *

Though many Minnesota physicians are under the impression that the Emergency Maternity and Infant Care program (EMIC) has been discontinued, actually it is still in operation but undergoing a gradual process of liquidation.

The U. S. Children's Bureau recently announced that maternity care is available only to those who were eligible on June 30, 1947—which means that all maternity care will be completed by the spring of 1948, although babies born to this group of patients will be entitled to

receive immunizations and care of illnesses during the first year of life, thereby not ending the EMIC program until the spring of 1949.

Eligibility for benefits under the program is based on three major qualifications: (1) the husband must be or have been in the four lower pay grades, or an aviation cadet; (2) he must have been in the service on or before June 30, 1947; (3) the wife must have become pregnant by June 30, 1947, and been pregnant at some time while the husband was in one of the four lower pay grades of the service.

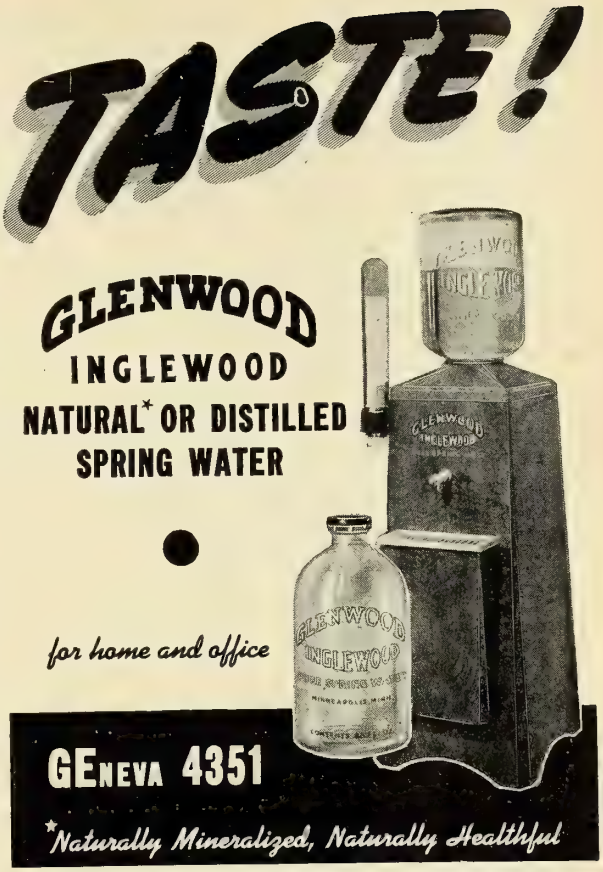
Physicians have been urged to accept these patients in order that the EMIC program may be completed without difficulty. Further information may be obtained from the Division of Maternal and Child Health, Minnesota Department of Health, University Campus, Minneapolis.

* * *

With the opening of a cancer detection center at the University of Minnesota Hospitals during the week of February 22, another weapon has been provided for the continuing battle against the disease which kills more than 400 Americans daily.

Under the directorship of Dr. David State, assistant professor of surgery at the University, the new center is being financed by the Minnesota Division of the American Cancer Society, the National Cancer Institute of the U. S. Public Health Service and the University's Malignant Disease Research Fund.

Not a clinic for providing treatment, the new cancer detection center is a place to which symptomless men and women of Minnesota, aged forty-five and over, may go for a thorough physical examination. If the examination reveals any indication of cancer or a pre-cancerous condition, the person examined will be advised to seek immediate treatment from his personal physician, and a report of the findings will be sent to that physician.



Any Minnesota resident, aged forty-five or over, can phone or write the cancer detection center for an appointment. A $5 registration fee is charged, though no one is turned away for lack of funds. The center is open two days each week, Tuesday for women, and Thursday for men, hours 8 a.m. to 5 p.m. Capacity of the center is between twenty and thirty persons each day. The complete examination requires a full day, and includes complete blood and urine examinations as well as a chest x-ray. When gastrointestinal x-ray studies are indicated, an appointment is made for a later date.

Wanted by Postal Authorities

The Post Office Department would like to obtain information leading to the arrest of an expert check forger named Jerome Poster, who also goes by various aliases. His eyesight is allegedly impaired by a recent self-inflicted injury, but the actual presence or extent of impairment of vision is questionable.

He is described as follows: age 24, height 6 feet, weight 186 pounds, chesnut-colored eyes, black curly hair, dark complexion, medium slender build. A dark brown mole is present on his right cheek. He is Jewish but looks Italian.

Anyone possessing information as to this man's whereabouts should notify Post Office Inspector F. L. Pierce, Saint Paul, Minnesota (Telephone: Cedar 8033, extension 446 or 428).

BLUE SHIELD NEWS

This is the first article written by the Minnesota Medical Service, Inc., to be published in MINNESOTA MEDICINE. Each month, a similar article will be published to bring to the physicians of the state the latest information on Blue Shield. We feel that the physicians of the state should be informed as to what is going on in regard to their "baby" and that they will be interested in its growth and development.

At the present time, more than 2,100 licensed doctors of medicine in the State of Minnesota have signed agreements to become Blue Shield participating doctors of medicine. With support like that the Minnesota Blue Shield cannot fail. To date there are 153 Blue Shield groups throughout the state, or 3,910 contracts in effect. That means that about 10,000 persons are protected by Blue Shield.

The first payment on claims was made on January 15, 1948. It was for $227.50 and covered nine cases. The February 15 pay-off was for $864 and covered seventeen cases. Thus far, we have paid twenty-six claims for a total of $1,091.50. It is anticipated that the March payments will well exceed the $1,000 mark.

The Blue Shield belongs to the doctors, and it is in their power to make it the best in the country or cause it to fail. The doctors of the state don't want a failure. Also, they do not want an organization that is not operated by professional men. As a result, the board

HOSPITAL NEWS

Staff officers of the following Minnesota hospitals were elected to office during January and February.

Wesley Hospital, Wadena.—At the annual meeting of the medical staff of Wadena's Wesley Hospital on January 7, Dr. C. W. Lewis of Henning was elected chairman of the medical staff. Named as vice chairman was Dr. E. C. Hanson of New York Mills, while Dr. Robert Pierce, Wadena, was elected secretary.

St. Mary's Hospital, Minneapolis.—Dr. F. B. Mach, newly appointed chief of staff of St. Mary's Hospital in Minneapolis, commenced his new duties on January 13 when the staff members held their first meeting of the year. A graduate of the University of Minnesota Medical School, Dr. Mach has been a member of the staff of St. Mary's Hospital for more than thirty years.

St. Luke's Hospital, Duluth.—Chief of staff of St. Luke's Hospital, Duluth, is Dr. Gordon C. MacRae, who was named to succeed Dr. A. O. Swenson at the annual meeting of the hospital staff on January 15. Dr. S. E. Urberg was elected to the office of vice chief of staff. At the meeting the following officers were named for two-year terms: Dr. S. H. Boyer, Jr., chief of medicine; Dr. P. N. Bray, chief of obstetrics; Dr. A. L. Abraham, chief of x-ray section; Dr. F. C. Jacobson, chief of anesthesiology, and Dr. M. H. Tibbetts, chief of orthopedics.

Eitel Hospital, Minneapolis.—It was announced on January 24 that Dr. Wallace I. Nelson had been elected chief of staff of Eitel Hospital, Minneapolis, to succeed Dr. Frank Hirschfield. Also elected to office were Dr. Alfred T. Baker, assistant chief of staff, and Dr. Melvin B. Sinykin, secretary-treasurer.

staff banquet on February 9, marking the sixth year of operation for Hibbing General Hospital, announcement was made of new officers elected for 1948. Chief of staff is Dr. C. N. Harris, while Dr. Andrew Sinamark is vice president and Dr. Robert A. Murray is secretary. Departmental heads include Dr. C. Jacobson, surgery; Dr. Randall S. Derifield, medicine; Dr. L. W. Morsman, ophthalmology; Dr. Sinamark, otolaryngology; Dr. B. F. Flynn, pediatrics; Dr. T. A. Estrem, obstetrics; Dr. Carlyle Tingdale, contagion; Dr. C. S. Raadquist, x-ray, and Dr. R. E. Hansen, laboratory.

Swedish Hospital, Minneapolis.—On February 14 it was announced that Dr. Reuben Erickson had been named chief of staff of Swedish Hospital in Minneapolis. Named as vice chairman was Dr. Lawrence Carlson. Listed as heads of various committees were Dr. Robert Quello, Dr. M. L. Fredlund, Dr. Hamlin Mattson, Dr. J. S. Milton, Dr. Horace Scott and Dr. H. I. Gustason.

* * *

"The Relationship Between Hospital and Community" was the title of an address by District Judge Mark Nolan at the annual meeting of St. Mary's Hospital staff in Duluth on February 5. Election of staff officers was held at a business session of the meeting. Dr. C. O. Kohlbry, chief of staff-elect, in 1947, succeeded Dr. L. R. Gowan as chief of staff of the hospital.

* * *

The Madison Hospital Association announced early in January that it had received a gift of a set of general surgical instruments and a promise of an x-ray machine as soon as the new hospital was ready for its installation. The gift and the promise were from three local physicians, Dr. Nels Westby, Dr. W. N. Lee, and Dr. Magnus Westby, and constituted a definite step forward in the development of hospital facilities in Madison.

In Rochester on January 12, at the annual meeting of stockholders of the Kahler Corporation, hope was expressed that an addition of Colonial Hospital would be completed by August. Officers and directors of the group were re-elected. They remain Roy Watson, president and general manager; C. N. Judd, vice president; H. J. Harwick, secretary-treasurer, and M. M. Hayden, assistant secretary, with the other directors consisting of W. W. Lawler, Dr. M. S. Henderson and Dr. P. S. Hench.

* * *

The Ely-Winton Community Hospital, formerly the Winton School, was being remodeled during February to become a memorial dedicated to Ely-Winton youths who died in World War II. Cost of conversion was expected to be $50,000, more than two-thirds of which had been raised through solicitation by the end of January. The completed hospital will have thirty-five beds. On the board of trustees are Dr. O. E. Snyker, chairman, Frank Romsich, Bernard Hutar, C. V. Hammerstrom, Mrs. Ruth King, Uno Saari and Urho Salminen.

* * *

A drive to establish a community hospital at Harmony got under way in January. At a public meeting, Stanley Todd was named chairman of a citizens hospital committee to organize and conduct the campaign. Among those named to serve on the committee was Dr. Carl G. Nelson, Harmony.

* * *

Among nursing and hospital leaders participating in a meeting at Saint Paul on February 2 were Dr. P. F. Eckman, Duluth, member of the state board of examination and licensure of practical nurses; Sister M. Vivian, O.S.B., director of nursing at St. Mary's Hospital, Duluth, and Miss Hazel Gabrielson, superintendent of nurses at St. Luke's Hospital, Duluth. The group heard a report made by the Minnesota Advisory Committee on Nursing on what is being done to remedy the nurses shortage in Minnesota.

* * *

Members of the hospital commission of Baudette were in Park Rapids on January 18 inspecting its one-year-old hospital and gathering information that would aid in the construction of the Baudette hospital. Included in the group were Dr. A. A. Brink and Dr. Charles E. Stafford.

* * *

For the thirty-first consecutive year, Dr. O. F. Mellby, Thief River Falls, has been elected president of the Oakland Park Sanatorium commission. His re-election took place at the annual meeting of the commission on January 9.

EXCELLENT CARE TO CONVALESCENT AND CHRONIC PATIENTS

Rates Reasonable. Patients under the care of their own physicians, who direct the treatment.

5511 Lyndale Ave. So. LO. 0773 Minneapolis, Minn.

Two radio talks on hospital construction were given in February by Dr. Viktor Wilson, chief of the Section on Special Services of the Minnesota Department of Health. Sponsored by the Blue Cross, in co-operation with the Minnesota Hospital Association and the Minnesota Nurses Association, the talks were entitled "Priorities for Your Hospital Building" and "Hospitals Where We Need Them," and were presented over station WTCN on February 9 and 23, respectively. Dr. Wilson reported the results of the state hospital survey, and gave information on the planning of new hospitals and the expansion of present ones, on the establishing of priorities for government grants for construction, and on the scientific placement of hospitals for best use.

* * *

The annual report of Oakland Park Sanatorium, prepared by Dr. B. A. Borreson, superintendent, showed that maintenance expenses of the institution increased considerably during the last year. Total expense of the sanatorium increased from $58,904 in 1946 to $65,865 in 1947, while total cost per day per patient increased from $3.57 to $4.30. Receipts in 1947 from state aid, paying patients, and other sources, amounted to $18,151.

* * *

Seven Waseca County physicians appeared before the Waseca city council on January 13 to urge improvement and enlargement of the Waseca Memorial Hospital.

Not asking for immediate action in expanding the eighteen-bed hospital to optimum size, the physicians suggested that construction of a small addition, large enough to store supplies and equipment, would make it possible to convert the present basement into hospital rooms for eight or ten patients. An increase in patients might enable the hospital to make expenses, instead of operating at a loss as it had during the last year, they pointed out. Optimum size of the hospital, to be aimed at when construction costs are lower and if financial aid can be obtained, would be forty to fifty beds.

The physicians present at the meeting were Dr. R. H. Davis, Dr. O. J. Swenson, Dr. S. C. G. Oeljen, Dr. H. M. McIntire, Dr. B. J. Gallagher, all of Waseca, and Dr. R. C. Hottinger and Dr. C. T. Wadd, of Janesville.

* * *

Minnesota Hospital Service Association elected the following officers at its annual board meeting on February 19: S. W. Pinkerton, Saint Paul, re-elected president; D. E. Bronson, Minneapolis, vice president; Dr. Peter D. Ward, Saint Paul, secretary; E. M. Jorgenson, Minneapolis, treasurer; and Harry E. Kern, Saint Paul, assistant treasurer.

HOSPITAL CONSTRUCTION PROGRAM FOR MINNESOTA

Details of a $25,000,000 hospital construction program, in which the Federal government would aid by contributing $8,300,000 over a five-year period, were announced late in January by Dr. Viktor O. Wilson, chief of the

Division of Special Services of the Minnesota Department of Health.

Under a plan recommended by a Minnesota hospital survey committee, the state would be divided into eleven regions, with the Twin Cities serving as a base area. The University of Minnesota Hospitals and the Medical School would be the principal base hospital for the entire state. The eleven regional hospitals would be in Crookston, Brainerd, Hibbing, Virginia, Fergus Falls, Duluth, St. Cloud, Willmar, Worthington, Mankato and Rochester.

Throughout the eleven regions there would be seventy-five "area" hospitals and thirty-nine "rural" hospitals, placing 98.5 per cent of Minnesota's citizens within twenty miles of adequate hospital facilities.

On the basis of the plan and according to results of a survey conducted in 1947, a priority list has been prepared for proper allotting of Federal funds to communities and areas to help finance the building and equipping of hospitals. The priority list is divided into four groups, according to the degree of need for facilities. In Group A are nineteen communities in which no hospital is located. Group B consists of thirty-six communities which have hospitals but no existing acceptable beds. Group C, also with thirty-six communities includes those with hospitals which need improvement or enlargement. The remaining thirty-five of the communities considered fall into Group D.

Opportunity to apply for Federal funds to finance one-third of the cost of construction and equipment will be offered according to priority number on the list, starting with Group A. After the opportunity is offered, community authorities will have thirty days to indicate a desire to construct a hospital under the terms of the plan. The community will then have sixty days to have preliminary plans drawn up and approved and to show ability to finance the project. An additional six months will then be allowed so that complete plans may be formulated and everything made ready for the start of construction.

If these deadlines are not met, the community loses its priority for the year and must wait until the following year before it can obtain funds. In the meantime, the opportunity is offered to the next name on the list.

Among requirements that must be met to qualify for receiving aid are (1) need for the hospital as shown in the state plan for hospital service; (2) public or nonprofit ownership of the hospital; (3) assurance by the owner that hospital service will be provided in the community without discrimination on account of race, creed or color; (4) assurance that services will be provided in reasonable amount to persons in the community unable to pay therefor; (5) ability of the owner to finance two-thirds the cost of construction; (6) ability of owner to finance the operation of the hospital, for which evidence must be provided; (7) ownership of a suitable site for the hospital, and (8) development of blueprint plans and specifications for construction by a registered architect in conformity with state and Federal regulations.

Communities receving the first nineteen priorities (Group A) are Pine River, Baudette, Sandstone, Cambridge, Aitkin, Forest Lake, Olivia, Le Sueur, Spring Valley, Grand Marais, Red Lake Falls, Sauk Centre, Blackduck, Elbow Lake, Wells, Greenbush, Karlstad, Floodwood and Zumbrota.

In Group B, receiving priorities 20 through 55, are Bagley, Long Prairie, Shakopee, Cook, Slayton, New Prague, Wheaton, Paynesville, Preston, Watertown, Buffalo, Winnebago, Anoka, Madison, Breckenridge, Pine City, Morris, Ortonville, Pelican Rapids, Cass Lake, Gaylord, Granite Falls, Mahnomen, Worthington, St. James, Moorhead, Blue Earth, Marshall, Deer River, Cloquet, Brainerd, Hastings, Springfield, International Falls, Two Harbors and Eveleth.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

TREATMENT BY DIET. Fifth Edition. Clifford J. Barborka, B.S., M.S., M.D., D.Sc., F.A.C.P. Assistant Professor of Medicine, Northwestern University Medical School, Chicago; Attending Physician, Passavant Memorial Hospital; Consultant in Gastro-enterology and Gastroscopy, Diagnostic Center, Hines Veterans Hospital; Formerly Consulting Physician, Mayo Clinic. 784 pages. Illus. Price, $10.00, cloth. Philadelphia: J. B. Lippincott Co., 1948.

BRIEF PSYCHOTHERAPY. A Handbook for Physicians on the Clinical Aspects of Neuroses. Bertrand S. Frohman, M.D. With collaboration of Evelyn P. Frohman. Foreword by Walter C. Alvarez, M.D. 265 pages. Price, $4.00, cloth. Philadelphia: Lea & Febiger, 1948.

OPERATIVE GYNECOLOGY. Sixth Edition. Harry Sturgeon Crossen, M.D. Professor Emeritus of Clinical Gynecology, Washington University School of Medicine; Consulting Gynecologist to Barnes Hospital, St. Louis Maternity Hospital, St. Luke's Hospital, De Paul Hospital and Jewish Hospital; and Robert James Crossen, M.D., Assistant Professor of Clinical Gynecology and Obstetrics, Washington University School of Medicine; Assistant Gynecologist and Obstetrician to the Barnes Hospital and St. Louis Maternity Hospital; Gynecologist to St. Luke's Hospital and De Paul Hospital. 999 pages. Illus. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1948.

DIABETES MELLITUS IN GENERAL PRACTICE. Arthur R. Colwell, M.D., Associate Professor of Medicine and Director of Medical Specialty Training, Northwestern University Medical School; Attending Physician, Evanston Hospital, Evanston, Illinois; Consulting Physician, Wesley Memorial Hospital, Chicago. 350 pages. Illus. Price $5.25. Chicago: Year Book Publishers, 1947.

In the most recent of the General Practice Manuals, the Year Book Publishers have presented a practical review on the subject of Diabetes Mellitus by Dr. Arthur Colwell of Northwestern University. An evaluation of this book must necessarily consider the value of the entire series. Their purpose is to give the general practitioner a concise and timely review of the subject in question, with emphasis on clinical application. In the reviewer's opinion, the series has proved of inestimable value to the acquisitive but busy practitioner who is attempting to keep pace with the many developments in the constantly changing realms of medicine. Some of the books in the series have fallen short of the aims of the publisher; others, among them Dr. Colwell's book, have accomplished their objectives remarkably well.

In *Diabetes in General Practice,* the author puts greatest emphasis on the management of the diabetic patient. He limits his discussion of the more academic questions of etiology, pathogenesis, et cetera, to the first forty-eight pages of his text; in the remaining 290 pages, he clearly and concisely sets down his recommendations on diabetic diet, desugarization, insulin administration, the management of acute complications, including diabetic coma and insulin shock, and, finally, the management of chronic complications. He places at the disposal of the busy practitioner an opportunity to gain insight in a few hours into diabetic problems that all too many busy doctors never adequately mastered. He does not fall into the error so frequently seen in medical writing, of covering his subject in so few words that the practical information sought is not set down.

The author does not afford himself space to present conflicting opinions on some of the points covered in the text. While, in some instances, this may lead to false premises, on the whole, it adds to the clarity and readibility of the book. His instructions for calculating the diabetic diet are sufficiently lucid to allow even the least dietary minded of physicians the opportunity to prescribe diabetic diets with a minimum of food lists and tables. The food tables presented in the text, together with the graphs showing the actions of the various insulin preparations, are, in the reviewer's opinion, the highlight of the book. The author covers the subject of insulin therapy thoroughly, including a good discussion of the use of insulin mixtures.

In the last two chapters of the book, the disease's complications and its effect on other diseases and bodily states are discussed. Diabetic acidosis is broken down into its grades of severity, and the methods of handling the various stages are considered. The important problem of diabetes in pregnancy is covered. Chronic complications, ideas as to their etiology, the possibility or impossibility of remedial care, and their management are carefully reviewed.

In summing up, it is believed that the book should serve to bring better diabetic care into the hands of the general practitioner seeking such aid. That it will not take the place of the more complete texts on the subject is obvious. It is highly recommended for its wealth of applicable information.

TUBERCULOSIS. Francis Marion Pottenger, A.M., M.D., L.L.D., Professor of Medicine, University of Southern California School of Medicine, Medical Director of the Pottenger Sanatorium and Clinic for Diseases of the Chest, Monrovia, California. 579 pages. Illus. Price, $12.50. St. Louis: C. V. Mosby Co., 1948.

The distinguished medical director of the Pottenger Sanatorium has again drawn on his very extensive experience to prepare a textbook on pulmonary tuberculosis. In this volume much of the later literature is reviewed and some of the newer concepts of phthisiogenesis are discussed. His views on the relationship of visceral neurology to pulmonary disease occupy two chapters, in which he has emphasized the value of the demonstration of reflexes originating in pulmonary pathology. Many physicians lack his skill in detecting and interpreting such reflexes. Four chapters are devoted to the time-honored methods of physical diagnosis, all of which will help in the accurate detection of lesions which have progressed to an extent appreciable by such measures. In minimal cases the diagnosis must often be made, without their aid, from a study of the patient's history, tuberculin tests, sputum tests, including gastric expression and serial x-rays.

The discussion of the treatment of pulmonary tuberculosis is practically a résumé of all the measures that have been in vogue thus far in the twentieth century, not all of which, including open air treatment, tuberculin and heliotherapy, are considered necessary or advisable in many cases today.

In his discussion of collapse therapy, the advantages of pneumothorax are enumerated as contrasted with other operative procedures, and special advantages are claimed for it. Rest of the diseased lung is, of course, the object of all collapse therapy, as the author has made plain. The modern thoracic surgeon has, as the author admits, several resources besides pneumothorax, and he must be called upon to use them in the individual case as necessity arises. No general regime will fit all patients. They are safest if under the constant close observation of a group of specialists, preferably in a sanatorium, and including an experienced chest surgeon.

The book contains much useful information. Physicians in charge of tuberculosis patients should also have access to other late books and the current literature.

Doctor's Home and Offices

In Anoka, a suburban city of about 8,500 inhabitants, situated at the junction of the Rum and Mississippi Rivers just 18 miles from Minneapolis, and 25 miles from St. Paul, a short drive on any of several well-paved highways.

Local business serves neighboring farm population which specializes largely in dairying, poultry and truck farming. In the past five years, Anoka and the area towards Minneapolis has had a steady growth in population and industry.

These choicely located offices and the adjoining beautiful red brick Colonial house are well located on the main street just a few steps from the Post Office and across the street from County Court House. The offices consist of two complete suites of three rooms and laboratory each plus a 10 x 17 waiting room. There are other clinical rooms available. The lovely six-room Colonial house has a 15 x 26 living room, dining room, breakfast room, kitchen and ½ bath on first floor. The second floor has 3 bedrooms—one of which is a large master bedroom—and tile bath. The basement has a bedroom and bath, also an amusement room. The property is on a well landscaped lot that is 99 x 248.

The retiring owner has practiced in Anoka for 21 years—he has lived and practiced in these premises for the past 10 years. It is his opinion that a good man, once established, should make $15,000 or more per year. He also would agree to stay on for awhile and help get a new man acquainted in the city.

It is our opinion that this is a real value. We believe that to acquire the land and reproduce the home and office thereon, would cost upward to $70,000 today. We are offering the property for $45,000.

MODERN NURSING

In step with the steady pace of progress, the modern student nurse can accomplish her training at Glenwood Hills in a modern stream-lined short course. Through careful selection of curriculum and employment of advanced teaching technics, it is now possible to present a complete course of instruction in as little as one year's time.

Short courses such as the one currently being offered at Glenwood Hills Hospitals have proven to be extremely valuable to the medical profession as well as the student. They furnish trained assistants to the doctors and hospitals in this area, and allow the trainee to quickly attain a producing status within her profession.

In spite of the increased number of nurses graduated from training schools during the last two years, the shortage is still acute. Your help is greatly needed. As a doctor, you can materially assist in this effort by enumerating the advantages of a nursing career to young ladies in your community. We respectfully suggest that you have prospective nurses in your acquaintance investigate our facilities.

FREE ILLUSTRATED BOOKLET

Clip the coupon below and hand it to the most likely candidate you know. On its return we will send an illustrated booklet explaining the school and the training course. She is obligated in no way by this act. It is obvious that more detailed information as to courses and facilities available must be put into the hands of the prospective trainee if nursing is to successfully attract an adequate share of young women. **By giving this coupon to an interested party, you will be assisting materially in the effort to increase the number of trained nurses available to the medical profession.**

The Balance Sheet

WE ARE all striving mightily to set aside some portion of our income in reserve. This is not an easy task in this day of heavy taxation. Yet these reserves are important; to be used for contingencies that we cannot predict today. It's silly to be forced to stand idly aside and watch those reserves being dissipated through protracted periods of disability when you could have prevented it by the purchase of an outstanding Disability Policy.

IT'S ONLY logic that indicates that your best plan of income protection is through the plan made available to you through your Association.

TOMORROW may be too late—ACT NOW.

Experience is the Best Teacher

William Stokes
(*1804–1878*) *proved it in cardiology*

Dr. Stokes' detailed treatises based on his own observations helped establish his reputation as a clinician. He thought, as his experiences increased, that others paid too much attention to physical signs, especially in valvular cardiac disease. He believed that the condition of the muscle was much more important than the state of the valves. Stokes' contributions greatly aided the advance of medical knowledge in cardiology.

R. J. Reynolds Tobacco Co., Winston-Salem, N. C.

EXPERIENCE IS THE BEST TEACHER IN CIGARETTES, TOO!

With the thousands and thousands of smokers who have tried and compared many different brands of cigarettes, Camels are the "choice of experience."

Try Camels yourself! Find out how much your taste appreciates the full, rich flavor of Camel's choice, properly aged, expertly blended tobaccos—how your throat welcomes Camel's cool mildness.

Let your own experience tell you why more people are smoking Camels than ever before.

According to a Nationwide survey:

More Doctors Smoke CAMELS
than any other cigarette

Three leading independent research organizations in a nationwide survey asked 113,597 doctors what cigarette they smoked. The brand named most was Camel!

ANNOUNCING...

THE NEW RAYTHEON *Microtherm* CONSOLE

For Modern Microwave Radar Diathermy

In the model CMD-5 Microtherm, Raytheon offers more than just Federal Communications Commission approval. It brings to the doctor *microwave radar diathermy* . . . a completely new, scientifically researched post-war tool which greatly expands the science of heat therapy.

Microwave diathermy offers the following features:

- A high degree of absorption.
- Penetrating energy producing deep heating.
- Produces a desirable temperature ratio of fat to vascular tissue.
- Effective production of active hyperemia.
- Desirable relationship between cutaneous and muscle temperature.
- Controlled application over large or small areas.
- Eliminates electrodes, pads and danger of arcs.

ACT NOW to give your patients the benefit of this great advance in diathermy treatment. Ask us to give you a demonstration of the new Raytheon Microtherm.

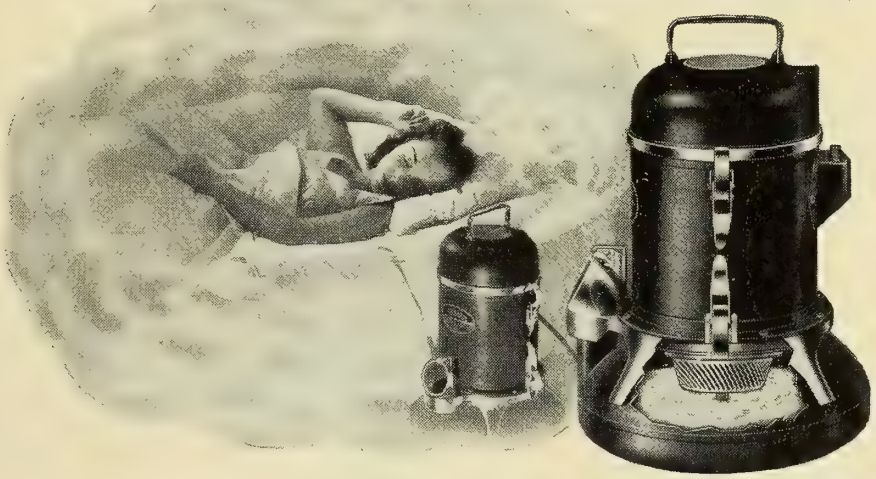
GOOD INSURANCE WHEN

Under-Nutrition THREATENS

When increased nutrient needs, finicky appetite, or food aversions threaten the nutritional state by limiting food intake, the delicious food drink made by mixing Ovaltine with milk is employed to advantage.

This nutritional supplement proves good insurance against an inadequate nutrient intake, since three glassfuls daily brings even an ordinary diet to optimal levels. It supplies generous amounts of all the nutrients considered essential: biologically adequate protein, B complex and other vitamins including ascorbic acid, readily utilized carbohydrate, easily emulsified fat, and important minerals. Adults and children both enjoy the delicious taste of Ovaltine. Hence it is readily taken by all patients in the recommended quantity.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.



Ovaltine

Three servings daily of Ovaltine, each made of ½ oz. of Ovaltine and 8 oz. of whole milk,* provide:

CALORIES	669	VITAMIN A	3000 I.U.
PROTEIN	32.1 Gm.	VITAMIN B_1	1.16 mg.
FAT	31.5 Gm.	RIBOFLAVIN	2.00 mg.
CARBOHYDRATE	64.8 Gm.	NIACIN	6.8 mg.
CALCIUM	1.12 Gm.	VITAMIN C	30.0 mg.
PHOSPHORUS	0.94 Gm.	VITAMIN D	417 I.U.
IRON	12.0 mg.	COPPER	0.50 mg.

*Based on average reported values for milk.

YOU HAVE NEVER KNOWN BEFORE

"WASHED" AIR IS WHOLESOME AIR

The moment you enter a Rexaired room, you will notice how fresh the air is; how comfortable it is to breathe. Rexair is the amazing new appliance that actually improves the air you breathe.

Rexair takes dust from carpets, bare floors, drapes, upholstered furniture, and from the air itself. Rexair collects dust and dirt in a water bath; discharges cleaner and moistened air back into the room.

The longer Rexair runs, the cleaner and fresher the air becomes. Rexair has no porous bag from which dust can escape back into the air you breathe. Dust is permanently trapped in water. You pour the water down the drain—dust and dirt go with it.

Illustrated at the top of the page is a Rexair with the reservoir cut away to show the water which traps and holds dust so that it cannot escape. You feel better and work better when the air you breathe is clean, fresh, and wholesome.

"Protein destruction following injury"

"Certain types of injury produce a general reaction on the part of all tissues. An outstanding indication of such a reaction is an intense *protein breakdown* which begins soon after the injury and may last for several weeks thereafter. *Fracture* of the major bones, *extensive burns*, *abdominal trauma*, and some *operative procedures* are the most common offenders in this regard. The negative nitrogen balance which follows injury is difficult to compensate for. *Extremely high protein* intakes are needed to minimize the loss of bodily tissue. It should be remarked that in the case of burns, protein is lost not only by excretion via the urine, but also the oozing of protein-containing fluid from the injured skin surfaces."*

When protein supplementation presents a problem . . . SWIFT'S STRAINED MEATS

When soft, high-protein diets are indicated, many physicians now use Swift's Strained Meats. These all-meat products provide a palatable source of complete, high-quality proteins, B vitamins and minerals. Originally developed for infant feeding, the meats are strained fine enough to pass through the nipple of a nursing bottle—may easily be used in tube-feeding. Swift's Strained Meats are convenient to use—ready to heat and serve. Six kinds: beef, lamb, pork, veal, liver and heart. Three and one-half ounces per tin.

Also Swift's Diced Meats—for high-protein diets requiring foods in a form less fine than strained, these tender, juicy cubes of meat are highly desirable.

**From "The Importance of Protein Foods in Health and Disease," the new, physician's handbook on protein feeding. This booklet, prepared by a physician, in conjunction with the Nutrition Division of Swift & Company, is available to you without cost. Simply fill out the coupon below.*

FOR STERILE PENICILLIN

STERILITY TEST—*one of 138 separate tests made by Abbott in the production of dependable penicillin:* Six tubes, each containing 15 cc. of sterile culture medium, are used. Tubes 1, 2, 3 and 4 receive 1 cc. of a solution of 100,000 units of penicillin dissolved in 10 cc. of hydroxylamine hydrochloride. This chemical compound inactivates penicillin so that its antibiotic power does not influence sterility findings. Tube 4, in addition, receives 1 cc. of a 24-hour culture of *Staphylococcus aureus* to show whether penicillin had been inactivated. Activity of *S. aureus* is tested by tube 5, which receives 1 cc. of bacterial culture only. Tube 6 receives 1 cc. of hydroxylamine hydrochloride to test sterility of inactivator. All six tubes are incubated at 37° C., observed on 2nd, 4th and 7th days. (F.D.A. requirement, 4 days.) Typical tests results: Tube 6 remains clear, showing inactivator was sterile. Tube 5 grows out (becomes cloudy with bacteria), showing that *S. aureus* is active. Tube 4 grows out, proving that penicillin in it and in Tubes 1, 2 and 3 had been inactivated by hydroxylamine hydrochloride. Tubes 1, 2 and 3 remain clear, showing that no bacterial growth has taken place and penicillin is sterile.

FREQUENT, exacting and varied tests—138 in all—protect Penicillin Abbott in the course of production. These 138 Abbott tests, in addition to those conducted by the Food and Drug Administration, are your assurance that Penicillin Abbott can be used *with confidence*. From mold to finished product, the tests include not only sterility but also potency, pyrogens, toxicity, penicillin G content, heat stability, pH, moisture content, solubility and crystallinity. As a result, Penicillin Abbott is absolutely dependable—whether in cartridges, vials, troches, tablets or ointments. Remember the name ABBOTT for penicillin needs. The First Specialized Dentistry

Dentistry was only a "sideline" for goldsmiths, blacksmiths and strolling barbers until the French and American Revolutionary era. France demanded schooling for dentists in 1697; and Pierre Fauchard (1690-1761) soon reported systemic infection caused by teeth, used pivot teeth and crowns and made dentures complete with artificial gums.

Two favorite figures of the American Revolution symbolize the "before" and "after" of the *dental* revolution. Paul Revere was rendering dental services in addition to his smithing and engraving in 1773, while George Washington's dentures (illustrated above) were carved from a hippopotamus tusk by a full-time dental *specialist!*

But doctors still had no specialized *protection*. In 1794, in the first American malpractice case to be appealed, the defendant had no trained malpractice attorney to defend him and no malpractice insurance to pay his judgment.

Doctors Today need not depend, for their protection, upon companies offering malpractice insurance as just another "sideline." *Specialized* malpractice protection—*complete, preventive and confidential*—has been assured by the Medical Protective policy since 1899.

For More Rapid Desensitization of the Hay-Fever Patient

PYRIBENZAMINE

The prophylactic administration of Pyribenzamine hydrochloride prior to a desensitizing dose of allergen has proved successful in the prevention of constitutional reactions.[1] By using Pyribenzamine routinely during desensitization therapy, it is possible to make greater increments of dosage, thereby reducing the total number of injections required.[2]

Likewise, in the prophylaxis and treatment of allergic reaction to liver extract, penicillin, the sulfonamides and certain other drugs, Pyribenzamine has proved efficacious.[1, 3]

RECTALGIA ASSOCIATED WITH INTESTINAL DISEASES

Symptomatic Treatment

J. ARNOLD BARGEN, M.D.
Rochester, Minnesota

AMONG the most trying conditions encountered in the management of intestinal disease is the anal discomfort which so frequently occurs as a major complaint. This discomfort is trying not only for the patient but for the physician as well. Frequently the anal condition so overshadows the basic problem that much effort is wasted and valuable time is lost by directing all attention to the local anal discomfort instead of to the more serious and important disease in more proximal segments of the bowel.

However, experience has taught physicians that it is unwise to direct all the attention to the care of the intestinal disease, for the patient's comfort inevitably assumes an important place in the efforts to control a severe infectious intestinal disease or even the unpleasant sensations associated with the irritable bowel syndrome. Both may be associated with very uncomfortable anal tenesmus or other forms of rectalgia. Once the anal discomfort is controlled, or at least ameliorated, the major problem may be attacked more leisurely or at least with greater confidence from the standpoint of both the patient and the physician.

One may actually be surprised to see a severe diarrhea subside or lessen with the control of a patient's anal disorder, albeit this may have little direct bearing on the treatment of the disease causing the diarrhea. It is rarely wise to indulge in any reparative anal surgical procedure in the presence of intestinal disease but the importance of establishing anal comfort sometimes by the most simple means cannot be overrated. The need for control of anal discomfort has often assumed such major proportions that many symptomatic measures have been invoked including hot Sitz baths, anal irrigations and a variety of local medicaments. It has long been known that ethyl aminobenzoate (benzocaine) has a particularly soothing effect when applied to the anal region of these sufferers. The problem of the method of its application, however, has not been easy. When prepared in the form of a rectal suppository, it can be readily inserted by the patient himself. A suppository containing a soothing mixture of benzocaine, oxyquinole sulfate, balsam of Peru and ephedrine hydrochloride in cocoa butter has proved suitable.*

Three groups of patients with as many types of symptoms have been particularly helped by this type of suppository: those patients with the anal tenesmus and rectalgia associated with the irritable bowel syndromes, those with the misery of severe anal infection and those with the diarrhea of infectious intestinal disease. In a group of patients who were afflicted with chronic ulcerative colitis and who had rather severe diarrhea, decrease in the number of stools occurred in at least half the cases after use of this type of suppository. Table I illustrates this change in a small group of patients. Similar results have been obtained in a much larger series of cases.

The following is a report of a series of cases in which is illustrated the nature of the problem for which anal relief was obtained. (The case numbers follow consecutively those in Table I.)

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

*Material used in this study was rectal medicone, supplied by The Medicone Company, 225 Varick Street, New York City, New York.

TABLE I. EFFECT OF RECTAL SUPPOSITORIES ON RECTAL DISCOMFORT IN CHRONIC ULCERATIVE COLITIS WITH RATHER SEVERE DIARRHEA

Case	Suppositories Used, Days	Decrease in Stools in 24 Hours	Rectal Discomfort
1	9	7 to 3	Relieved
2	9	6 to 2	Pain and soreness relieved
3	15	13 to 9	Slight soreness relieved
4	8	8 to 4	Slight soreness. No improvement
5	8	5 to 3	Relieved

Report of Cases

Case 6.—A woman, twenty-five years old, who had had chronic ulcerative colitis for three years with a rectal stricture which had reduced the lumen to about 5 mm., inserted one of the suppositories into her rectum three or four times a day. The patient obtained relief from the burning after stools and then ceased passing two or three small, loose stools after each main stool. She thought the suppositories relaxed the rectum and thus made her more comfortable.

Case 7.—A girl, fourteen years old, had had chronic ulcerative colitis involving the entire colon for two years. The roentgenogram showed more involvement of the mucosa than of the deeper structures of the wall. The disease was not very active but there was tenesmus for an hour after each bowel movement. This discomfort was completely relieved after several insertions of suppositories.

Case 8.—A woman, thirty-six years of age, who, for two years, had had chronic ulcerative colitis which involved the rectum and sigmoid and which was associated with much rectal tenesmus, inserted the suppositories into her rectum. Relief of the discomfort caused by the tenesmus followed promptly.

Case 9.—A man, forty-six years of age, had had chronic ulcerative colitis for six months. The disease involved the rectum and sigmoid severely, with minimal changes in the entire colon. He complained of rectal burning after bowel movement, which was relieved by the suppositories.

Case 10.—A man, thirty-four years of age, who had had chronic ulcerative colitis for ten years, came to the clinic with far-advanced disease, a rectal stricture having reduced the lumen to about 1 cm., and with a fistula in ano. He had a very tender and sore anus. Much of this soreness was relieved by the use of the benzocaine suppositories.

Case 11.—A man, thirty-one years old, who had had regional enteritis for six years, came to the clinic with a history of having had a hemorrhoidectomy in 1932, an operation for a fistula in ano in 1937, a right hemicolectomy and resection of the ileum for regional enteritis in 1941, an operation for two fistulas of the rectum in 1942 and an operation for a fistula of the rectum in 1946. Examination showed an inflammatory process of the rectum which extended as far as the proctoscope could be introduced. There was stricturing of the rectum which had reduced the lumen to 1.5 cm. at a point 6 cm. from the anus. There was a subacute abscess and a draining sinus in the perineum. Roentgenologic studies revealed, at the site of anastomosis, recurrent enteritis associated with an inflammatory process in the colon. The patient's anorectal discomfort was almost unbearable. He obtained great relief by insertion of a suppository after each bowel movement.

Case 12.—A man, forty-six years old, who had had a severe diarrhea for seven years, came to the clinic for examination. A segmental colitis of the ascending and transverse colon was found and a proctoscopic examination revealed anal ulceration. The bowel seemed to be normal between the anus and midpart of the transverse colon. The anus was tender and painful. The patient became comfortable after using the suppositories for six days, one after each bowel movement, of which he had five daily.

Case 13.—A woman, forty years of age, came with the complaints of an irritable colon with which she had been troubled for six years. Her discomfort had been aggravated by a hemorrhoidectomy. She complained of a pressure sensation in the rectum which had been getting gradually worse. Insertion of the suppositories into the rectum after bowel movements resulted in complete relief of this symptom.

Any relief from medication of this type is purely symptomatic. However, it becomes much easier for the physician to control the other more serious lesion after the patient's suffering from anal discomfort has been wholly or partly relieved.

There may be other substances the use of which will result in similar relief. In this study, ethyl aminobenzoate (benzocaine) in a suitable formula in the form of a suppository has been of striking help in allaying anal discomfort. It is likely that patients with other painful anal conditions might be benefited by the use of such a suppository.

PROCTOLOGY AND THE GENERAL PRACTITIONER

WILLIAM C. BERNSTEIN, M.D.
Saint Paul, Minnesota

UPON my return to civilian practice after three years in the armed services, I was struck by the fact that a great many general practitioners were fearful that the present trends in medicine would limit the field of usefulness and activity of the general practitioner. I feel that I have been on the scene long enough now to evaluate and to attempt to clarify the situation insofar as the specialty of proctology is concerned.

Although proctology is one of the newer and younger specialties, it is already apparent that as knowledge and experience are accumulated, the field of activity of both the general practitioner and the specialist is rapidly widening. We are aware that a very large percentage of patients have symptoms referable to the lower gastrointestinal tract; since approximately 4 per cent of adults harbor precancerous adenomata or polyps in their rectum and colon, and since approximately 15 per cent of all cancer occurs in the rectum and colon, it is apparent that herein lies a very fertile field for action on the part of both general practitioner and proctologist. We need but take an active and sincere interest in patients with symptoms referable to the lower gastrointestinal tract and we will find that our field of usefulness will be greatly increased.

I believe that it is well to survey the situation as it exists today. Every large city and many small ones have advertising doctors who prey upon persons afflicted with anal, rectal and colonic complaints. These irregulars enjoy very large and lucrative practices despite the fact that their work is very mediocre or, in fact, very poor. Why, then, do the patients continue to patronize them? To my mind it is apparent that so many physicians are content or feel inclined to dispose of their rectal patients with nothing but a very cursery examination and a prescription for one of the many over-advertised suppositories or ointments, that the patients shop around until they find a doctor who makes an outward appearance at least of real interest in rectal or bowel disorders.

If we were to limit this discussion to the subject of constipation alone, we would be dealing with a condition that probably afflicts more people than all other diseases put together. The proceeds from the sale of laxatives and cathartics in this country are greater than those from cosmetics and far in excess of the proceeds from the sale of any other medicine. Still, we as a profession are doing very little about it. The study of all constipated persons who come to us for help would uncover many pathologic conditions, including cancer, and the application of intelligent treatment would improve the health and minds of many of these patients who are spending their lives in relative invalidism. It is in this direction that many of us should bend our efforts in the future.

Certainly it is to the general practitioner or family doctor that most patients go with their early symptoms. The general practitioner is in the very best position, therefore, to provide early and effective service in preventive medicine, cancer detection and treatment of early lesions. His field of usefulness need be limited only by his knowledge and experience.

The family physician is also the one on whom most families depend for advice and counsel when a member of the family learns that he has a cancer of the bowel and will need a radical operation with or without the establishment of a colostomy. Upon the moral support of the family physician depends the entire future mental comfort of the patient. Most physicians have had experience in the care of patients with colostomies and know that an intelligent patient need not be handicapped to any great extent by an artificial anus. The family physician should be the one to inform the patient and his relatives that the average patient with a colostomy usually becomes adjusted to his new life in a short period of time and learns how to take care of himself without the use of bags, diaphragms, plugs or other appliances. Once a patient learns from his own medical counsellor that, with a colostomy, his bowel can be trained to empty once or twice a day and remain clean the rest of the day, he is in a much better frame of mind to accept his new lot. It is indeed unfortunate when the family physi-

Read at the annual meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 8, 1947.

cian informs the patient that a colostomy is a rather horrible substitute for a normal anus and that it should be avoided at all costs. Needless to say, no conscientious surgeon would advise the establishment of a permanent artificial anus if he did not feel that it was an absolute necessity in ridding the body of a malignant growth. Patients with artificial openings, either colostomies or ileostomies, require more or less constant medical supervision. They can be handled well by the general practitioner who manifests an interest in their problems.

Most patients who are operated upon for cancer of the rectum and colon have had symptoms for more than ten months. They have been treated with suppositories and internal medications and have had hemorrhoidectomies and other rectal operations. We know, of course, that it would be much better for these patients if a thorough and adequate workup were to be done early rather than late in the course of their disease. Proctoscopic and sigmoidoscopic examinations should be available for all patients who present themselves with early symptoms referable to the lower gastrointestinal tract. No longer is the digital rectal examination considered an adequate rectal investigation. Only by means of a well-conducted proctosigmoidoscopic examination of the rectum and lower sigmoid regions can early lesions of these parts be ruled in or out. There are many general practitioners who are now doing excellent proctosigmoidoscopic examinations. The technique is not too difficult to master, but inasmuch as there are some tragic hazards connected with the procedure, one should become thoroughly familiar with the technique before subjecting the patient to this examination. Once one becomes familiar with the appearance of the normal rectum and sigmoid colon, a new world of pathology unfolds itself. One can learn to recognize such lesions as early neoplasms, ulcerative colitis, multiple polyposis, amebic dysentery, bacillary dysentery, lymphopathea venerea and numerous other bowel conditions.

The use of the x-ray in examinations of the lower gastrointestinal tract is well recognized by all physicians. I feel, however, that there are two points in this connection which should be emphasized. The first is that the barium enema examination should be used much more frequently and earlier in the course of the patient's illness than is generally practiced today, and the second is that the interpretation of a barium enema examination requires much training and experience. I feel that too many persons entirely unprepared to make this interpretation are attempting to examine these patients and are missing many early lesions. The fluoroscopic phase of a colon examination, in particular, should be performed by a well-trained roentgenologist. If a patient receives a negative report of his barium enema examination when, in fact, he has an early lesion in his colon, he may well have lost his one and only chance for early and complete cure of his cancer.

The diagnosis of the common anorectal conditions, such as hemorrhoids, fissures, abscesses and fistulas, is not difficult. These diseases are usually accompanied by either pain, bleeding, discharge or some type of protrusion or swelling. Every patient should be given the benefit of a well-taken history and thorough examination. The practice of having a patient bend over and "spread his cheeks," as was practiced in so many of the army and navy examinations, can no longer be condoned. I am happy to say that, in many centers, this type of examination has been replaced by adequate anoscopic and proctosigmoidoscopic visualization of the parts. In the group of conditions just mentioned, the general practitioner should be able to diagnose and treat all but the difficult or complicated ones.

I wish to mention specifically one disease, to make clear the point that there is much room for greater activity in the field of proctology. One of the most common complaints that is presented to either the general practitioner or proctologist is itching about the anus. In my own practice, one out of every four patients has pruritus as one of his chief complaints. The average physician seems to be afflicted with the same feeling of despair that most patients have concerning this condition. I do not share this feeling. Although the etiologic factors concerned in pruritus ani are numerous, it is possible after a well-taken history and examination to learn much about the cause in many patients. Personal hygiene, perianal infection (anal fissures, infected anal crypts, hemorrhoids, fistulas, et cetera), fungus infections, allergic reactions and psychic disturbances all play important roles in this disease. Once the cause is determined and the treatment applied, the patient may obtain gratifying relief. Only in a relatively small percentage of cases is it necessary to use

DIVERTICULITIS OF THE COLON

WILLIAM G. SAUER, M.D.
Rochester, Minnesota

DIVERTICULA may arise along the entire length of the gastrointestinal tract and may be classified as either true or acquired diverticula. The so-called true or congenital diverticulum contains all the intestinal layers in their normal relationships. Meckel's diverticulum of the ileum is an example of this type. My discussion today is concerned with acquired diverticula. In this type of diverticulum the sac of mucosa has herniated through the wall of the intestine, and the muscular layers cover only a portion of the diverticulum and are relatively thick near the base of the pouch but sparse over the apex. Generally, the mouth of the sac which opens into the lumen of the intestine is small in relation to the remainder of the sac. The occurrence of one or more than one sac in the large intestine often is spoken of as diverticulosis. When these sacs are involved in an inflammatory process the diagnosis of diverticulitis is made.

Etiology

Many theories have been devised to explain the manner in which diverticula appear in later life. The most commonly mentioned of these is concerned with herniation of intestinal mucosa near the points of entry and exit of the blood vessels and lymphatics along the mesenteric border of the bowel. Contradictory to this theory is the fact that these saclike outpouchings also occur along the antimesenteric border and the lateral walls of the colon. It has been proposed that other factors, such as increased intracolonic pressure, the process of atrophy in the musculature of the aging intestinal wall and localized changes in the resisting power of the wall, may account for the formation of diverticula in any part of the colon. Henderson has suggested that diverticula appear during or after an attack of inflammation in a section of the colon and it is this initial inflammatory attack, or series of attacks, which constitute a mechanism that brings about weakening of the wall. As a result of his personal observations at operation and in roentgenograms, Erdmann considered that these diverticula are of congenital origin though some may be acquired. Fansler stated that diverticula appear more frequently along the antimesenteric border, and that as a consequence of degenerative changes muscular weakness develops. Trauma caused by hard stools and gaseous distention eventually produces herniation of mucosa through the weakened portion of the intestine and a diverticular sac is thus formed.

Incidence

It is generally agreed that diverticulosis occurs with advancing age. Bargen has found that diverticulosis rarely occurs before the age of thirty-five years and it is estimated that about 95 per cent of the patients are fifty years of age or older. It is frequently stated that obese individuals are more likely to have diverticulosis of the colon than thin persons. The sex incidence varies from equal distribution among males and females, to a preponderance of 4:1 in males, in Erdmann's experience. Young and Young in 1944 compiled statistics from the literature and found diverticulosis in 5.2 per cent of 70,572 colons examined at necropsy or roentgenographically.

Diverticula may appear anywhere in the various segments of the colon. They may be present diffusely along the entire length of the bowel or may occur singly or with gradations between these extremes. They are uncommon in the rectum and are most frequent in the sigmoid and descending colon. Dixon, Deuterman and Weber found that 60 per cent of all diverticula of the gastrointestinal tract are in the sigmoid.

Pathology

Diverticula communicate with the lumen of the intestine and are capable of filling and emptying. When a hardened mass of fecal material occludes the narrow neck of the sac, edema of the mucosa with obstruction to emptying occurs. With retention of the contents and consequent irritation of the mucosa, inflammation occurs and the process of diverticulitis is at hand. From this stage there are several possibilities as to the future course. The inflammation may subside and

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.
Read at the meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 8, 1947.

the episode is then over. Should this not occur, one of several conditions may develop.

Bacterial peritonitis may develop from extension without perforation of the inflamed diverticulum. However, this is rare. The inflamed sac may rupture and produce acute peritonitis. The inflammation may spread to involve the intestinal wall and other diverticula and thus produce the condition known as "peridiverticulitis," with narrowing of the lumen of the intestine and eventual obstruction after repeated attacks. A localized abscess may occur as a consequence of the inflamed diverticulum's perforation. Fistulas between the inflamed region and the bladder, the vagina, the abdominal wall or other intestinal segments may develop. Arnheim has collected statistics from cases reported in the literature and has found some significant figures which follow.

Perforation with formation of abscess occurred in 19 per cent and peritonitis in 12 per cent of 834 collected cases. Formation of fistulas occurred in 8 per cent of 1,516 cases; the sigmoidovesical fistula was relatively frequent and more common in diverticulitis than in carcinoma of the sigmoid. Peridiverticulitis with narrowing of the lumen of the intestine and tumefaction occurred in 20 per cent of 1,049 cases. Metastatic suppuration as a complication of diverticulitis is rare and Arnheim found only three cases reported in the literature. Abscesses were reported in the liver, lung, brain and mesenteric, splenic and portal veins in these cases. It is the consensus that carcinoma bears no etiologic relationship to diverticulitis, though the two conditions may coexist.

Rarely do diverticula occur singly in the cecum and ascending colon. When inflammation occurs in such a solitary diverticulum, the process in the right portion of the colon resembles acute appendicitis clinically. At operation it sometimes is mistaken for perforating carcinoma. Its infrequent occurrence is attested by the fact that Carroll in 1943 found only forty-three cases reported in the literature. Abscess with or without perforation was common in the solitary diverticulum, and widespread peritonitis was rare in these cases. When classification into true or acquired diverticula was attempted, he found that the diverticulum in most cases was of the true type, with the normal layers of the colon in normal relationships in the pouch or sac.

That diverticulosis must exist before diverticulitis develops is generally agreed on. However, the incidence of diverticulitis in cases of diverticulosis is not definitely known. Many figures are given in the literature. According to Dixon, Deuterman and Weber, it is generally accepted that in about a fifth of the cases of diverticulosis diverticulitis will develop.

Diagnosis

Since the course of diverticulitis may run the gamut from a single attack of acute diverticulitis through the various situations just described to formation of a fistula, it is readily apparent that the symptoms, and physical and laboratory findings may vary immensely.

When uncomplicated diverticulosis exists, complaints vary from none at all to constipation, diarrhea, cramps, irritability, abdominal pain and occasionally even bleeding per rectum. This variation is so great that the relationship of these complaints to roentgenologic finding of diverticulosis may be questioned. There are no positive physical findings which indicate uncomplicated diverticulosis.

During an attack acute diverticulitis resembles acute appendicitis except that the symptoms are referable to the left lower quadrant of the abdomen. Pain of an intermittent cramping type is the common symptom, and it is usually aggravated by cathartics. Defecation may temporarily relieve the pain. Vomiting may occur. There is tenderness and occasionally rigidity of the left lower quadrant to palpation. There may be fever. Leukocytosis of the order occurring in acute appendicitis may be present but its presence depends on the extent and severity of the attack.

When perforation has occurred, cramping lower abdominal pain usually is present and is associated with chills and fever. Urinary symptoms often are present and consist of dysuria and frequency. A mass may be palpable in the left lower part of the abdomen. Should the process progress, formation of a fistula into the bladder, vagina, other loops of bowel or the abdominal wall may occur. The passage of cloudy urine and gas at the end of urination through the urethra is diagnostic of perforation into the bladder with formation of a fistula. The formation of sigmoidovesical fistula is usually due to diverticulitis rather than to carcinoma. Of fifty cases of sigmoidovesical fistulas studied by Bar-

gen, in thirty-one the fistulas were due to diverticulitis and in nineteen to carcinoma.

In some cases in which repeated attacks of diverticulitis occur or the initial process continues over a long period, the bowel wall in the involved region becomes thickened. Patients with this condition have recurrent bouts of abdominal pain, fever of varying degree, and a change in bowel habits usually toward progressive constipation. A mass may be palpable in the involved region and ultimately obstructive symptoms develop if the condition persists long enough.

The incidence of rectal bleeding in cases of diverticulitis varies greatly according to several authors. It is variously given as 5 to 17 per cent, though Young and Young found blood in the stools in 26 per cent of their eighty-four cases of diverticulitis. No other cause for bleeding could be found in these cases. Rosser, Fansler and others have emphasized that bleeding may occur in association with diverticulitis, while Nash and Palmer stated that in their experience rarely if ever can bleeding be attributed to diverticulosis or diverticulitis.

Special examinations which aid in establishing the diagnosis include sigmoidoscopy and roentgenologic examination of the colon. Sigmoidoscopy may reveal sacculation of the sigmoid and the mouths of the diverticular sacs may be seen. Roentgenologic examination of the colon may manifest a number of findings indicative of the condition. Examination after a barium enema which demonstrates the presence of diverticular sacs is of obvious value. The presence of various roentgenologic signs including serration, narrowing of a long segment of sigmoid with no destruction of the mucosa and obstruction to retrograde flow indicate various stages of diverticulitis to the roentgenologist. Differentiation between diverticulitis and carcinoma of the sigmoid is most often first made by a competent roentgenologist.

Treatment

Treatment of diverticulitis consists principally of medical management; surgical procedures usually are reserved for the complications. When the diagnosis of diverticulosis is made, efforts are advanced to prevent the occurrence of inflammation in the diverticula and consist of institution of a bland, nonconstipating diet and administration of mineral oil. Regular intestinal habits should be cultivated.

The acute attack of simple diverticulitis is best managed by placing the patient at rest in bed. The colon is placed at near rest by providing a liquid diet for the first few days. Heat is of value and may be applied by means of diathermy and hot wet stupes to the abdomen. Rectal instillation of warm oil for retention will supply heat. One of the sulfonamides, such as phthalylsulfathiazole (sulfathaladine), should be administered. The patient should be carefully watched until signs of tenderness over the involved region, usually in the left lower quadrant of the abdomen, subside. After the acute phase has subsided, the program used for management of diverticulosis is resumed gradually.

When the process has progressed to the point of obstruction, the patient receives treatment directed at decompression of the obstructed intestine. Fluids are not given by mouth but are administered parenterally. Heat is applied to the abdomen. With the patient in the knee-chest position, rectal irrigations may be given carefully. Intestinal intubation and suction drainage of the intestine may be needed. When the symptoms of obstruction are controlled, management is as described for the attack of acute diverticulitis. When medical management fails to relieve the obstruction, surgical intervention and colostomy become necessary.

Likewise, when abscess perforates, surgical intervention is necessary, but only after the acute symtoms subside in the majority of cases. Here also preliminary colostomy seems the treatment of choice. As a general rule, it may be stated that the establishment of a colonic stoma indicates the need for later colonic resection of the involved region. Treatment along medical lines before establishment of a colonic stoma should be employed only until the acute symptoms abate and should not be prolonged. This treatment is generally the same as employed in the obstructive type of diverticulitis, with the exception that rectal irrigations should not be used.

Prognosis

After the diagnosis of diverticulosis is made, it seems that progression to diverticulitis might occur less frequently than it does, if proper management were instituted.

The prognosis in cases of uncomplicated diverticulitis is good. Brown[3] and Brown and Marcley,[4] reporting on 1,100 cases of diverticulosis, included data on 99 cases of diverticulitis in which surgical treatment was employed and on 227 cases in which treatment was medical. Sixty-three per cent of the patients treated medically obtained excellent results while the remaining 37 per cent obtained only fair or poor results. However, many patients in the latter group lived fairly comfortably. Of the surgically treated patients, 57 per cent had excellent results.

In Brown and Marcley's series adequate follow-up was available in 192 of a total of 700 cases of diverticulosis. Diverticulitis had occurred in one of 192 cases.

Thus it may be said that the prognosis in cases of diverticulosis is excellent. The prognosis in uncomplicated diverticulitis is good, but the outlook for those patients who have complications of diverticulitis may be serious.

PROCTOLOGY AND THE GENERAL PRACTITIONER

(Continued from Page 364)

radical treatment in the form of alcohol injections or anal neurectomy. The conscientious general practitioner could well afford to spend much more time with these patients than he does at present. The promiscuous use of suppositories and proprietary ointments in pruritus ani should be condemned. Only an intelligent investigation of the individual patient, with properly applied treatment, can bring satisfaction to both patient and physician.

A word of caution might well be injected at this time. It is extremely easy to be carried away by one's enthusiasm or to become overly optimistic about certain forms of treatment after a few successes. In proctology there are certain procedures which can be done well as ambulatory or office procedures. Each case should be decided upon its own merits, and the physician should not be influenced too far by the patient's desires. The injection treatment of hemorrhoids is a good example. If this treatment is limited to the cases for which it is indicated, good results may be anticipated. If, however, the patient insists on having his hemorrhoids injected, simply because Dr. Brady has stated that the ambulant treatment of hemorrhoids is satisfactory or because some friend has had the injection treatment and liked it, the results will be far from good. The injection treatment of hemorrhoids was never intended to be an adequate treatment for all kinds of hemorrhoids. Similar statements can be made regarding the ambulant treatment of other rectal conditions.

The patient who has suffered from anorectal disease, be it a painful external hemorrhoid or a fistula of long standing, and has obtained relief is the most grateful patient one can find. If the general practitioner would only realize this fact, he would devote much more time and effort to the care of these patients. There need be no cause for alarm that the general practitioner's field of usefulness will be narrowed. In the limited field of proctology alone there is an almost unlimited opportunity for men in general practice to widen their scope of activity in making earlier diagnoses and in treating early lesions. In the long run, the general practitioner will not only better his own professional status but will take away the incentive and necessity for patients to patronize the advertisers and other cultists.

HEMOSTATIC AND ABSORBABLE DRESSINGS IN ANORECTAL SURGERY

JAMES KERR ANDERSON, M.D., F.A.C.S.
Clinical Associate Professor of Surgery, University of Minnesota
Minneapolis, Minnesota

ANORECTAL surgery, of necessity, is carried out in a very vascular field. Any agent which will assist in the control of postoperative bleeding and oozing may well be added to the means at hand. In the past several years, absorbable hemostatic dressings have been placed on the market and have been used fairly extensively in many fields of surgery. Owing to the hemostatic properties and the size of the dressings, they are most adaptable to anorectal procedures. We have been using them for over a year with complete satisfaction and feel that they are worthy of consideration and use.

This report will be limited to a discussion of only one of these products, the one which we have used in some 200 cases of hemorrhoids, anal fissure, fistula, perineal resection and pilonidal disease. This product is a sterile, absorbable oxidized cellulose pad, sold under the name, Oxycel, and manufactured by Parke, Davis and Company. This material was first prepared by Kenyon and his associates,[9,10] in the Eastman Kodak Laboratories, and has been subjected to extensive laboratory investigation to determine possible irritating properties and rate of absorption from various animal tissues. Using a special technique devised for testing various absorbable materials, Frantz et al[3,7] found that implants in connective tissue, muscle, bone, serous and synovial cavities, brain, thyroid, liver, kidney and spleen were completely absorbed in varying lengths of time, depending on the amount of material introduced, extent of operative trauma and amount of blood present. Gruhzit et al[6] have observed the absorption rate of this dressing when implanted in various tissues. These investigators describe the disintegration and absorption in the following manner: "When implanted in tissue or when in contact with tissue fluids or blood, it forms coagulum. In this manner it produces local hemostasis. Following the initial hemostatic effect, it is quickly changed into a dark brown, soft mass, which in turn, becomes jelly-like colloidal material. Subsequently, the jelly-like mass becomes thin, forming a water like, pigmented fluid which either diffuses or is taken up by phagocytosis into the general tissue fluid circulation."

Frantz[4] states that following implantation of the dressing, no appreciable clot forms in the meshes of the gauze. According to Gruhzit,[6] the initial lesion formed at the site of the implantation consists of a multilocular nodule or cyst surrounded by a coagulated tissue membrane. As it becomes lysed and absorbed, the coagulum is surrounded by a zone of fibroblasts and invading large monocytes. Absorption is usually followed by some connective tissue scar formation. Frantz and Lattes[5] observed no acute inflammatory reactions following implantation of the dressing unless there was associated infection or some irritating foreign material present. The only untoward effect noted was when the dressing was implanted in bone. Burns[1] reported that oxidized gauze implanted in the omental bursa of the dog was completely absorbed in approximately twenty-eight days; while a piece the same size when placed among the intestines was completely absorbed in two days. In his opinion, absorption varies with the amount and type of peritoneal fluid present and the mechanical motility of the surrounding tissues.

The specific hemostatic property of oxidized cellulose seems to depend on formation of a coagulum consisting of salts of polyanhydroglucuronic acid and hemoglobin.[5] There is also quite a little swelling when it becomes moist with tissue fluids so that it adapts itself to wound spaces and acts as a packing agent by pressure.[6] These dressings are prepared from gauze by a special oxidation process with nitrogen dioxide which converts the unoxidized cellulose into polyanhydroglucuronic acid which is absorbable and hemostatic. The pad should be used immediately after the glass container is opened and removed with sterile forceps.

As brought out by Rosser,[8] the ideal postoperative anorectal dressing should have the following characteristics:

Read at the annual meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 8, 1947.

1. It should be a true dressing of individual wounds, not a pack or plug.
2. It should permit free drainage of secretions.
3. It should have a hemostatic effect without undue pressure.
4. It should permit the early escape of gas from the bowel.
5. It should be removable without pain.

I feel that the agent being discussed fulfills these criteria for postoperative anorectal wounds, and may be used in pilonidal and perineal wounds with success. It is not a substitute for suture or ligature and is of no use in active arterial bleeding. I like this dressing particularly well in cases of anal fissure, where a deep posterior incision is made with a plastic repair or marsupialization of the skin edges; by this I mean a broad triangular wound with the base outward, towards the coccyx, the skin edges being sutured down to the wound edges, not into the bottom of the incision. Bleeding is controlled by suture, and the dressing, as delivered from the container, is placed snugly in the open wound and through the anal canal. This is a pack of course and partly occludes the anal opening, but not sufficiently to prevent the escape of gas and even soft stool, as evidenced by the fact that many patients have bowel elimination while the pack remains in place. Over this hemostatic dressing in the wound is placed a piece of rubber dam, about 6 inches square, followed by gauze to give pressure, all of which is held in place by adhesive strips and a T binder. The external gauze, rubber dam and binder are removed eight to ten hours following operation and are not replaced. The cellulose pack soon becomes black and appears as a well-organized clot, becoming drier and more friable and smaller each day, some breaking off and being expelled. Owing to the friability, the pack cannot be removed intact. It usually has entirely disappeared in four or five days, during which time the wound has been held open and the edges apart, which is essential to the proper healing of this type of wound. After the pack has entirely disappeared, the wounds are dressed in the regular way, being kept apart and allowed to heal only from the bottom up. Previously used packs of gauze adhered to the wound, causing bleeding and pain when removed, and were most uncomfortable when in place. I feel sure that our fissure patients have been much more comfortable since we have been using these absorbable dressings.

If there are two fissures or ulcers in the anal canal, as is occasionally the case, requiring two incisions, I place the full dressing, as described, in the posterior incision and one half of a dressing in the other, which is usually anterior, followed by the rubber dam pack, et cetera.

With fistulas, the same technique is carried out after the wound has been properly saucerized, with all tracts dissected out and the bleeding controlled. The pack or packs are applied to fill the cavity. They remain in place until the outer dressings are removed or a Sitz bath is taken. Then they become loose and fall out, certainly with the first defacation, unless the wound is quite deep. At times, the packs may have to be removed piece by piece to allow proper healing. I have never noted any complaint when these packs have to be removed, as was the case when dry gauze was used. They are moist, shrunken, friable and do not adhere.

With hemorrhoids, we do a dissection type of procedure, involving four or five linear incisions. This cellulose dressing should be used against the anus, not in the anal canal, and should be covered with a rubber dam, some dry gauze, adhesive tape and binder, as mentioned above. The entire dressing, including the cellulose portion, should be removed in twenty-four hours unless disturbed by an undesired elimination. The cellulose does not adhere to the anal incisions and usually falls off when the outer dressings are removed. We have not had any postoperative bleeding from external hemorrhoidal incisions since using it. An alternative method which is sometimes used, is to cut the dressing into small strips, ½ inch wide and the length of the incision, and place one of these strips against each incision, the rubber dam being placed against these strips with the regular gauze dressing on top, all held in place by tape across the buttocks.

In office cases, where external thromboses are removed including all the vessels down to the sphincter, one small hemostatic strip is placed over the incision, covered with dry gauze and a snug binder.

In many cases of hemorrhoids there is also an accompanying stenosis which requires widening the anal canal by a deep posterior incision. If

this procedure is carried out, the wound resulting is similar to that of a fissure and is treated likewise.

In procedures for pruritus ani, where undercutting of the perianal skin is done through multiple linear incisions, this dressing is used as with hemorrhoids.

In pilonidal wounds, after the cyst has been removed, the base of the wound is packed with the cellulose dressing, which is placed so that overlapping of the skin edges is avoided. Over this, the usual gauze is applied, the wound being left open with the edges marsupialized. The entire pack is left in place until it falls out, or is removed when of no further use in the treatment. This new dressing has been particularly useful in these cases, as there is usually quite a little oozing which cannot be controlled by ligature.

In perineal resections, troublesome oozing is sometimes encountered about the prostate, vesicles and posterior vaginal wall. These packs have been applied directly to these areas, the wound closed, and healing has occurred without any infection.

It is evident that proper use of this new hemostatic dressing will change the usual methods of controlling anal bleeding by packs and pressure. In fact, some proctologists have abandoned the use of any internal dressing in simple anal cases to avoid pain and difficulty in expelling gas. These new dressings offer an almost painless and effective precautionary measure.

In conclusion, it may be said, while meticulous hemostasis is most important, this oxidized cellulose dressing is a valuable addition to present methods.

The dressing is nonirritating, but until in solution it constitutes a foreign body.

The product fulfills the requirements for an ideal postoperative dressing in anorectal cases.

REPORT ON CANCER DETECTION CENTER

Of the 108 persons, fifty-nine men and forty-nine women, examined in the University of Minnesota's new Cancer Detection Center during the first four weeks of its operation, forty-nine were found to have abnormalities requiring medical attention, Dr. David State, director of the center, reported April 1.

Examinations conducted by University specialists in the detection clinic disclosed, according to Dr. State: one definite case of cancer, twelve suspicious tumors requiring further diagnosis, nineteen pre-cancerous lesions, twenty benign (non-malignant) tumors and thirty non-tumorous conditions such as high blood pressure requiring immediate medical attention.

A large percentage of the forty-nine persons who were referred to their personal physicians for treatment, were found to be suffering from two or even three different conditions requiring medical attention, Dr. State explained.

Detection center doctors found that fifty-nine of the 108 persons examined were in good health and required no treatment. These persons, however, were advised to return to the clinic for physical examinations every six months to keep themselves assured that they are free of cancerous or pre-cancerous conditions.

More than 3,500 applications have been received for admission to the center for examination, Dr. State reported. At the present rate at which the center is able to operate, it will require two years to examine all who have applied.

"If persons who have made appointments desire to be examined before they can be accommodated at the University's Cancer Detection Center," Dr. State advised, "they should visit their personal physicians for a thorough physical check-up."

A project of the University's medical school, the Cancer Detection Clinic is financed in part by the Minnesota state division of the American Cancer society, the National Cancer institute of the United States Public Health service and the University's malignant disease research fund.

The center is open to men and women of Minnesota in the age bracket in which cancer most frequently occurs, forty-five and over, who are without symptoms of cancer. The center is operated on an appointment basis, and examinations are conducted on Tuesdays for women and on Thursdays for men.

A $5.00 registration fee is charged each person who is examined, but if a patient is unable to pay, he is asked to pay as much of the fee as he can.

The Cancer Detection Center is located in a temporary barracks-type building on Church street just west of University Hospitals.

SEROLOGIC OBSERVATIONS IN THE TOXEMIAS OF PREGNANCY

R. T. LA VAKE, M.D.
Minneapolis, Minnesota

TWO years ago, before this Academy, in a paper entitled "Serology and Obstetrics," data were presented in support of the hypothesis that the true toxemias of pregnancy are diseases caused by cell substances from the products of conception that are toxic to the cells of the pregnant woman, if they can gain access to her blood. Adequate proof of this causation in each instance demands that one demonstrate in the fetus a cell substance, such as the A, B, Rh substance, et cetera, not possessed by the cells of the mother; and that one demonstrate that the severity of the manifestations of toxemia in the mother varies indirectly with the strength of a demonstrable specific antitoxin in the mother. The proof parallels the nature of proof of disease caused by some bacteria or snake venom.

I have been asked to report any further developments accruing from two more years of work on the subject.

The hypothesis seems to demand a change in our understanding of the significance of blood group composition and cell substance status of human blood. The findings suggest that the inherited agglutinogens and isoagglutinins are not mere static morphological characteristics allowing the differentiation of humans into four groups. They are parts of a larger functional toxin-antitoxin mechanism. The potentially toxic elements are represented by the cell substances such as the A, B, Rh, M, N, et cetera; and the isoagglutinins, inherited or actively generated, represent the agglutinative arms of specific antitoxins, the other arms of the antitoxins being the lytic arms and the opsonic arms. It has long been known that in autopsies, following death from the transfusion of incompatible blood, the cells of the donor are not only agglutinated, but hemolysed and phagocytized. The same linked phenomena have been demonstrated *in vitro*. The phenomena paralleled those long known to occur when certain bacteria are attacked by a specific anititoxin. Obstetrical findings would suggest that a kinship exists between these two sets of parallel phenomena: that they are not strange to each other, as heretofore taught, demanding that we explain blood hemolysis by the presence of inherited unassociated hemolysins, that, however, for some unknown reason, tend to parallel in strength the isoagglutinins, and demanding that we explain the stimulated phagocytosis by the presence of unassociated, so-called hemotropins, that, however, are group specific. The hemolysins, isoagglutinins and so-called hemotropins represent the arms of specific antitoxins as in bacteriology. From the obstetrical findings it would seem logical to assume that the blood group compositions existing in our infinitesimal segment of evolutionary time are the result of the acquired inheritance of complements of antitoxic substances specific against certain cell substances that are toxic to the cells of individuals not containing these cell substances. This inheritance favored survival where the products of conception, due to the bisexual mechanism of human reproduction and under genetic laws, chanced to contain cell substances toxic to that mother.

The right to associate the time-honored isoagglutinin with an antitoxin was immediately challenged. When you suggested that erythroblastosis in the child was likely due to a specific anti-A, anti-B or anti-Rh antitoxin, whose high titer could be proved by titering its agglutinative arm, you were told that this rise in isoagglutinin titer was merely a manifestation of an antibody reaction to the implicated agglutinogen from the child. The isoagglutinin could in no way be associated with an antitoxin, nor could an agglutinogen be associated with a toxin.

The question arose as to what further proof could be devised that would tend to show that we were really dealing with a toxin-antitoxin reaction and that the isoagglutinin represented but the agglutinative arm of a specific antitoxin. It suggested itself that if it were a maternal antitoxin that injured or killed the baby in erythroblastosis or allied injury, then, by analogy and prediction, one should be able to injure or kill a rattlesnake by administering rattlesnake antitoxin to the snake. Here the snake could be considered as an aggregation of cells, as are the products of conception, or an aggregation of specific bacteria, the cells containing the cell substances of their com-

Read before the Minnesota Academy of Medicine, Saint Paul, Minnesota, December 10, 1947.

mon ancester: in the first two instances, the fertilized ovum, and in the last instance, the original bacterium. In collaboration with Dr. W. J. Breckenridge, director of the Natural History Museum of the University of Minnesota, these experiments were consummated, and, as predicted, the vital cells of the snakes were injured histologically and the snakes succumbed. Whatever the value of this work, it is being continued in the reasoned hope that, by analogy, it may throw some light on the question whether such diseases as progressive muscular dystrophy, and many others, may be due to maternal antitoxin action suffered by the fetus during intra-uterine life: that though we may ostensibly save the erythroblastotic child by proper transfusion, basic injury may have been sustained which may manifest itself later in life.

Obstetric and serologic data in relationship to true pregnancy toxemia and erythroblastosis fetalis suggested the assumption that the natural or inherited isoagglutinins, arms of inherited antitoxic substances, had likely gradually become inheritable because their inheritance favored survival of both mother and child and obviously the species, and at the same time made possible the gradual breeding into the species of even toxic cell substances in the inscrutable interests of evolution. It seemed logical from an ontogenic analysis, in point of time of the appearance of the group cell substances in the fetus, in strength sufficient for demonstration, and the appearance of the inherited isoagglutinins, that it must take from eight to many more times longer for a specific antitoxin to become widely inheritable in a species than for the cell substance to become widely incorporated as inheritable. The group substances become demonstrable around the thirty-seventh day of gestation, according to Kemp (this is about the time that nausea usually begins, and that fact may be significant), and the isoagglutinin inheritance does not manifest itself until well after the birth of the child. It seemed from known data that the A substance was likely the first to enter the species, then the B substance, and it was reasoned that the substances comprising the Rh group, and likely many others, had entered the species at a date so late in evolutionary time that enough time has not yet elapsed for their specific antitoxins to become inheritable. This reasoning was similar to that followed by uniformitarianism in geology: in the serologic problem, that the serologic sculpture of the past could be explained by the natural forces, such as are evidenced in the active immunization against the Rh substance and the active increase of immunization against the A and B substances, still operating in the present.

This assumption was immediately challenged. It was said to smack too much of the ideas of Lamarck and Luther Burbank, a rationalization that was completely outmoded. There was no evidence that there was any natural force, environmental or otherwise, that could influence the genes. The A and B substances arose as mutations, and likewise the natural isoagglutinins must have arisen by mutation. Mutation has become a handy, fashionable, time-and-thought-saving hypothesis.

Again in collaboration with Dr. Breckenridge, an attempt was made to throw some light on this rationalization by serologic studies of two well-known snakes.

It is estimated that king snakes and rattlesnakes have lived in juxtaposition for possibly ten million years. That the king snake is today relatively immune to the bite of the rattler is known. It is not a wild assumption that had the king snake not developed a hereditary immunity he would not exist today in rattlesnake environment. The question suggested itself as to whether the invulnerability arose from the situation that a rattlesnake's cell substances might be similar to those of a king snake and thus harmless when injected through its venom. Venom is saliva, likely, from our findings, containing the basic cell substances of the snake, as the saliva of human secretors contains the group cell substances of the individual. Or was the invulnerability due to the king snake having evolved an inheritable antitoxin to the rattlesnake venom? In a measure it was a problem paralleling the bite of the placental villi of a fetus. If the cell substances of the fetus are similar to those of the mother, a true toxemia will not develop. If an O group mother engenders a group A child, by a group A husband, she has a relative immunity due to her complement of inherited anti-A antitoxin.

It was found that both rattlesnake red cells and king snake red cells were agglutinated by rattlesnake antivenom. This was interpreted as showing that both snakes had one or more cell substances in common. This parallels the finding that, in human blood, both group O, Rh positive

cells and group A, B, or AB, Rh positive cells are agglutinated by Rh antitoxins.

Using the same elements for comparison, it was found that the king snake serum agglutinated the red cells of the rattlesnake, but the rattlesnake serum did not agglutinate the red cells of the king snake: just as group O serum will agglutinate the red cells of groups A, B, and AB, but the serum of these three groups will not agglutinate the red cells of group O. Thus the king snake's relative invulnerability would seem to be due to an inherited antitoxin or antitoxins specific against the toxic cell substances in rattlesnake venom. The rattlesnake has not had to evolve antitoxins against the cell substances of the king snake because the king snake is not a venomous snake.

Now if one species can develop a hereditary antitoxin to the cell substances of a different species, it should not do violence to one's reasoning to allow that a hereditary antitoxin can be evolved by a group within a species, a group whose cells are susceptible to toxic cell substances of other groups within the species, especially considering the fetus-mother relationship throughout pregnancy.

If the inheritance of cell substances and specific antitoxic substances are dependent upon genes, and all evidence so indicates, then new inheritable substances and antitoxic substances must depend on a change in the genes. It is an opinion that when we call a new substance or feature a mutation, as the term is generally understood and used, we are ignoring forces that have long been operating from the immediate and possibly the connected environment. When the manifestations of the consequences of this change become perceptible to our senses, we call it a mutation. But it is a gradual evolution, most of which is not demonstrable. The presence of inherited specific antitoxins in human blood seems to me to give a clue to some of the forces that change genes. It is an opinion that an anti-A or an anti-B inheritable antitoxic substance would never have appeared in human blood had the genes from which they stem not been gradually influenced in some way either by the circulating A or B substances or by the gradual and desultory impact of actively generated antitoxins.

For the obstetrician, both in practice and theory, the advantages of an understanding of the fetal cell substances hypothesis of the causation of the true toxemias of pregnancy is of great everyday value. It seems to permit one, by analyzing the cell substance status of husband and wife, to predict more accurately whether or not she is likely or not likely to develop a true toxemia. Similar cell substances in husband and wife is the most auspicious setup. The cases warranting especial supervision are those in which the husband's cells contain a cell substance or cell substances not possessed by the wife. The adequate proof of a fetal cell substance toxemia permits one to render a more reasoned prognosis as to the possible safety of a future pregnancy. A group O, Rh positive woman, for example, may have an almost fatal toxemia with a group A Rh positive child and later have many pregnancies with group O children without a sign of toxemia. Furthermore, if she develops a high antitoxin titer or relative immunity in her first A cell substance toxemia and again becomes pregnant with an A group child before her antitoxin titer or relative immunity has much diminished in strength, she may show few or no signs of toxemia. This acquired high relative immunity likely accounts for the statistical finding that true toxemia is less frequent in multiparas than in primiparas. It furnishes a probable answer to the question of why a woman may show severe manifestations of toxemia when she begins to absorb a dead fetus or may almost completely absorb the products of conception without a subjective or objective sign of toxemia. Other things being equal, the difference depends upon whether the cell substances of the products of conception are toxic or nontoxic to the mother. To those of us who long believed from clinical findings that the absorption of autolyzing placental infarcts were the primary cause of true late toxemia, it suggests that the toxin-antitoxin battle at the front line, the placenta, is the cause of the distinctive infarcts. Their autolysis, at least theoretically and logically, should increase the toxemia by liberating large quantities of the involved toxic fetal cell substance or substances.

The main importance of this hypothesis lies in the clear direction that it gives to the development of specific antitoxins, to be used, in the interests of the mother, either after the intrapartum death of the child in an adequately proven true toxemia, or after the delivery of a live child, or in postpartum eclampsia. It is true that the more widespread and increased attention to prenatal care and to early and meticulous rational empiric

treatment has appreciably reduced the frequency of eclampsia and, in general, reduced the morbidity and mortality of pregnancy toxemia; yet the fact remains that, at times, the earliest and most meticulous application of the most rational treatment is unsuccessful and might logically be bettered if specific antitoxins were available for use in the type of cases under discussion.

Discussion

Dr. L. W. Barry, Saint Paul: This is quite a profound subject. I should like to ask a few questions. Have you used any antibodies in the treatment of these cases? Have you worked out the blood grouping and titer in all of these cases? What is the mechanism underlying the mutations which you mention? Is the production of the antibodies described a protective mechanism on the part of the mother or child, or both?

Dr. E. F. Robb, Minneapolis: Dr. La Vake has certainly given us something to think about this evening. Three years ago the Rh question seemed to be something rather simple, but as time has gone on, many more factors have been introduced into the subject, and I, personally, am very much confused about it. Perhaps Dr. La Vake is about twenty years ahead of us now. Also, it seems to me that there might be a possibility that the Rh factor may have a part in some of the poorly understood diseases that we see today, namely, nephrosis, leukemia, et cetera. Certainly, Dr. La Vake's paper has been most enjoyable.

Dr. La Vake, in closing: In answer to Dr. Barry, it must be emphasized that we are discussing only cases considered to have been adequately proven. For example, an O group Rh positive woman with a group A Rh positive husband, begins to develop signs of toxemia; the expectant mother's anti-A and anti-B antitoxins are titered and it is found that the anti-B antitoxin titer remains stable while the anti-A titer begins to fluctuate or is above normal. In such cases, one can predict with a high degree of accuracy that the child belongs to group A. After delivery, the mother's anti-A antitoxin will tend to accumulate and its titer will rise. The faster and higher it rises, the more rapidly will the signs of toxemia in the mother recede. The titer will rise sometimes six or more dilutions. The pattern of recession of signs of toxemia parallels the pattern of recession of signs of injury observed after giving rattlesnake antitoxin to a subject of rattlesnake bite. This elevation of titer gradually subsides, but if it is still relatively high when this mother bears another group A child, the mother may manifest few or no signs of toxemia. This acquired relatively high immunity likely accounts for the statistical finding that toxemia is less frequent in multiparas than in primiparas.

At present, the practical importance of these investigations lies in their value in segregating cases most likely to develop toxemia and in prognosticating the safety of chancing future pregnancies. Their main importance would seem to lie in the clear and logical direction that they give to the possible development of specific antitoxins that may be used in the interests of the mother after the intrapartum death of the child in toxemia, or after the delivery of a live child, and especially in eclampsia. In 1926, McMahan reported, in a series of ten cases, a high percentage of improvement when treating toxemic patients with the sera of women who had just recovered from a toxemia. At that time no explanation could be given for the improvement, nor for the failures. Data now at hand would indicate that we are dealing with a toxin-antitoxin mechanism, and that to be helpful the serum must contain the antitoxin specific to the cell substance antigen involved.

In regard to pediatrics and Dr. Robb's discussion, it has long been held that one may use blood of any group in transfusing newborns because in the early months the hereditary isoagglutinins have either not yet appeared or are so weak that there is no fear of agglutination. This is true from the standpoint of the immediate danger of agglutination. However, if the findings under discussion have any directive significance, it would seem unwise, except in emergency, to give an O group infant either A, B or AB blood. This because of their possible, even subclinical, toxic effect. Where possible, blood of the infant's own group should be given. Many cases have been reported of disease reactions resulting even from the intramuscular injection of incompatible blood. Such reactions can be logically explained only if one accepts the hypothesis that such blood is potentially toxic to that individual.

Again, assuming that the fetal injury observed in erythroblastosis and allied conditions is the result of the action of maternal antitoxins during intra-uterine life, it would suggest that many early degenerative diseases, such as progressive muscular dystrophy, et cetera, may stem from the permanent underlying injury to fetal cells sustained during pregnancy. There is clinical evidence that not only can maternal antitoxins injure the fetus, but that, as fetal cell substances can injure maternal cells, so, at times, maternal cell substances may injure fetal cells.

INFLUENZAL MENINGITIS TREATED BETTER WITHOUT SPINAL PUNCTURE

Recovery from influenzal meningitis is more prompt and complications are fewer when treatment by spinal puncture is omitted, according to Archibald L. Hoyne, M.D., and Rowine Hayes Brown. M.D., in the February 28 issue of *The Journal of the AMA.*

Rare in adults, the influenzal meningitis was formerly almost universally fatal. The sulfonamide compounds, specific anti-influenzal serum and streptomycin have all made the picture more optimistic, but even today there is no standard accepted for their application. Many doctors still believe that numerous spinal taps for drainage are necessary even after diagnosis has been established by spinal tap. Furthermore, when the National Research Council released streptomycin for treatment it advised that the new antibiotic be injected by spinal puncture.

The authors' conclusion is based on a dozen years of experience in the treatment of meningitis. In their article they report specifically on fourteen consecutive patients with influenzal meningitis treated at the Cook County Hospital in 1946 and 1947 and sixteen consecutive patients treated at the Chicago Municipal Hospital in 1946. There was only one death in each group, and in both of the fatal cases the patients had been given streptomycin by spinal puncture as well as intramuscularly. On the other hand, twenty-three of the twenty-eight patients who recovered had received no treatment by spinal puncture after diagnosis. These twenty-three had been given streptomycin intramuscularly, had been treated with serum, or had received sulfonamide compounds—sometimes all three.

THREE MONTHS IN A STATE MENTAL HOSPITAL

ARTHUR T. LAIRD, M.D.
Duluth, Minnesota

SENSATIONAL articles regarding the shortcomings of mental hospitals have been appearing here and there in various magazines during the past four or five years. Quite a number of them do not seem to me to be entirely unbiased, but rather to be attempts, by emphasizing defects and magnifying distressing situations, to produce an altogether unfavorable impression.

Undoubtedly, mental hospitals have been handicapped and hampered in various ways, especially during the war and in these postwar days of high prices and high wages. They have been overcrowded, and replacements of certain old and unsanitary buildings have been impossible. It has been difficult to secure reliable personnel including physicians, because of the failure of legislatures to provide increased salaries and wages and more attractive living accommodations to compete with the inducements for outside employment.

The public should be aroused to the crying needs of the hospitals, but not by misrepresentation of facts or unfair criticism of conscientious and capable public servants who are carrying on a most important work under very difficult circumstances. The ethics of such exaggerations, even for the purpose of improving conditions, are open to question.

We are fortunate in Duluth in being located near the new and well-equipped state hospital for mental diseases at Moose Lake, which was first ready for occupancy in 1938. The site was well chosen. It is on a large level tract of land, comprising several hundred acres, just south of Moose Lake and only a mile and a half from the village of Moose Lake. The hospital has had the advantage of careful planning in advance and is not the result of gradual growth.

The main building and the three-story brick cottages are attractive and dignified architecturally and are connected by sunny corridors above ground. The pleasant entrance, comfortably furnished lobby and attractive offices give the newcomer a pleasant first impression. The color schemes and the plants and pictures used in the interior decoration of the halls and corridors are restful to the eyes. Soothing and carefully selected music is often heard in the halls. Close by are a beauty shop for women patients, a barber shop for the men, occupational therapy rooms, a store, in fact, many of the facilities found in a small village.

I had been aware of all this from previous visits to Moose Lake, but in January, 1947, I decided to see for myself just what was going on in the wards and private rooms. I knew that the superintendent had had difficulty in securing sufficient physicians, so I applied for a position as an untrained assistant for a period of three months. I hoped during this time to add a little to my very limited knowledge of mental diseases.

When I began my work on January 17, the institution was not overcrowded. It has a capacity of 1,000 beds, and the daily census during my stay was usually under 980.

In the main building are two admission divisions, one for men and one for women. These are located on the second floor and have accommodations for about sixty-five patients in small wards and private rooms. There is also a sitting room, dining room, really adequate toilet facilities, and an office. The corridors have linoleum floors, and the wards and private rooms terrazo flooring. They are easily kept clean, and there was no pronounced or disagreeable hospital order. All rooms were usually well lighted, heated and ventilated.

Patients are admitted on court order or as voluntary patients. A large proportion come from St. Louis County, others from Pine, Carlton, Itasca and Koochiching counties.

Both voluntary and committed patients enter the same divisions and receive similar care.

If in need of special medical attention and nursing, new patients are at once transferred to the hospital divisions on the fourth floor. Otherwise, after being seen by a physician, they receive routine care until the physical and mental examinations are completed. During this period the patient remains at rest, usually in bed, in a small ward or private room under the supervision of the physician in charge of the division, and

Read before the medical staff of St. Mary's Hospital, Duluth, Minnesota, September 4, 1947.

in the immediate care of the nurses and attendants.

Included in the staff at present are two physicians in addition to the superintendent and the first assistant, both of whom are experienced psychiatrists. They make the mental examinations and mental diagnoses.

The number of cases requiring emergency care or needing close hospital supervision varies from day to day. Under ordinary circumstances there would not be more than about twenty. Daily charts with temperature records, laboratory tests, x-ray findings, record of treatments given, physicians' and nurses' notes are kept up for them just as in a good general hospital. Penicillin and sulfonamides are freely used; blood levels are determined; intravenous infusions and blood transfusions are used as indicated.

The family is kept informed as to the seriously ill patient's condition, and provision is made for relatives remaining with the patient.

The nursing is done under the supervision of graduate registered nurses assisted by student nurses from various well-known hospitals who are receiving their three months of training in the care of mental cases. The graduate nurses also have the help of competent men and women attendants, some of whom have had special training or experience in the army or navy. Many of them are young married people and have homes in Moose Lake or vicinity.

I saw very little evidence of unkindness or inconsiderate treatment on the part of attendants. Any bruise of any kind must be at once reported to the main office, to the attending physician and to the superintendent, and an immediate investigation is made. Any attendant found treating patients harshly is promptly discharged.

A large proportion of the hospital patients are old people suffering from senile mental deterioration. Many of them have incontinence of urine and feces. Practically no homes and few hospitals are equipped to give such patients adequate care. They have to be lifted frequently and the linen has to be changed if they are to be kept comfortable and free from bed sores. This cannot be accomplished readily unless strong male attendants are available. In a private home, even if three trained nurses are employed in twenty-four hours, this is not always easy or possible, but it is part of the routine care at the state hospital.

There is a profusion of clean linen, and the change is made as often as the patient becomes soiled.

The food is abundant, of excellent quality, and is served as hot as possible from electrically heated carts which come from the main kitchen. Special diets for diabetics and other patients requiring them are provided upon doctor's orders.

One of the physicians is on call at night.

Besides visiting his hospital bed patients, the assistant physician must make daily rounds in the cottages where ambulant patients sleep. In one of these cottages on the men's side of the institution are about 125 patients who, while in fairly good general physical condition and able to be up and about, are not improving mentally and whose prognosis is not good.

In another cottage are about the same number of men whose outlook is more hopeful. Most of them are employed in the institution in various capacities.

There are two similar buildings on the women's side.

In conference with the nurses and attendants in charge, the physicians see patients in need of first aid or other medical attention. Clinics are held several times each week, to which the ambulant patients are referred for special attention. On Monday, the physician acts as a chiropodist or pedicure and also treats minor ailments or injuries. On Tuesday, new patients are vaccinated, given Mantoux tests, and anti-typhoid injections. Blood is secured for the routine Wassermann test. An x-ray of the chest is taken. All these procedures are for the protection of the patients themselves as well as employes. On another day a gynecological clinic is held.

In the meantime, courses of lectures are given to the student nurses, and regular mental conferences are held at which they are present.

Quite a complete variety of mental disorders are encountered.

The classification used is one which was developed in state mental hospitals and is included in the *Standard Nomenclature of Disease*. Its main subdivision of psychoses are those due to infection, to intoxication, to trauma, to disturbance of circulation, to convulsive disorders, to disturbances of metabolism, to disturbances of growth, nutrition or endocrine function, and to new growths.

I was interested to learn that mania, dementia

precox and paranoia are not clearly defined diseases in themselves, and that they cannot be attributed to definite tangible causes or structural changes. They are conditions or mental states which may or may not be present in various mental diseases.

Besides the psychotics, there were always patients who were in the hospital because of psychoneuroses which had rendered them antisocial. Quite a number of the young men had psychopathic personalities and had been committed for various sexual offenses. Some had been in the army or navy. In ordinary conversation with them, they seemed rational and intelligent enough. Perhaps they should not be sent in such large numbers to a state mental hospital. They are not wanted in the reform schools or state prisons.

The more excited and destructive patients were in the second floor divisions in the main building. All the windows in all buildings were well screened to prevent accidents and escapes. The doors leading to each of the main divisions and the cottages were kept locked. I had keys to all the wards, and as my duties took me to all of the men's divisions, I at first entered them with some trepidation but soon found that little effort was made by most of the patients to escape or to become unmanageable.

There are few conspiracies or attempts at concerted action. The patient is usually so self-centered and concerned with his own troubles that he pays little attention to the plans or movements of others.

After a few days I realized I was just living in a rather normal community. My fellow citizens were going about their own business but often gave me a friendly greeting. Some of them seemed a little peculiar, but I had met unreasonable folks before in Duluth and elsewhere.

Normal community life has therapeutic value for these mental patients and is promoted for this reason.

Religious services, community singing, patients' dances, amateur theatricals, ball games, movies, entertainments by local talent, and others provided by the University, are all included in "social activities." Attendance is a prized privilege and an incentive to good behavior.

The almost normal social life possible for many patients is rarely mentioned in articles criticizing mental institutions. To take advantage of it, one must of course be a reasonably good citizen or individual, and it is the purpose of all the treatment to transform the antisocial person into one who can safely be returned to his home environment.

Few persons regain mental stability unless they actually want to. Large numbers have never had it. Inheritance and environment and lack of early training have conspired to prevent normal mental development. The late Clifford Beers,[1] founder of the National Mental Hygiene movement, while he decried the inadequacies of mental hospitals, both public and private, in which he suffered much before he returned to his senses, and wrote his book, recognized that reforms in the hospitals were not the whole answer to the problem. In his work he had the co-operation of many institutional superintendents, and first and foremost, of Adolph Meyer, the dean of American psychiatrists.

The goal in the treatment of the individual patient is to get him to understand himself and control his emotional and volitional faculties. When their situation is fully realized, some patients can be influenced to take the proper steps to remedy their shortcomings. This, I understand, is the purpose of psychoanalysis and other forms of psychotherapy.

Aggravated cases are incorrigibly egocentric. The catatonic schizophrenic is content to let the rest of the world go by. He will stand rigidly all day long in one position, ignoring passers-by and seemingly taking a smug satisfaction in being self-sufficient. He has withdrawn or has escaped into a dream world of his own. Sometimes he can be shaken out of his lethargy for a time by shock treatment, but relapses are frequent.

Occupational therapy had its orgin in mental hospitals. In its broader sense it includes many of the activities carried on there.

To keep a patient constantly interested and occupied, so that he will have practically no time for morbid thoughts, is often a real problem. One important daily activity is eating, and the serving of well-cooked, warm and appetizing meals is an essential form of occupational therapy.

Simple tasks assigned to the patient soon after admission create interest which is still further developed as the patient becomes capable of assuming responsibility.

The men at Moose Lake at first help to polish floors, then to serve meals in the ward. They

assist in dressing and in caring for helpless patients, doing this under supervision. Later they are promoted to the cottages and help in the bakery, the laundry, and the power house, in work on the grounds or on the farm.

Large groups go in the morning and afternoon to the men's occupational therapy shop and do woodwork and painting, making very attractive and salable toys. Women patients help to keep their rooms and wards clean and do other work under the direction of the nurses. If found to be dependable, they serve food in the wards and in the employes' and staff dining rooms. They hem linens, mend worn garments, sort clothes, work in the laundry or sewing rooms and in the occupational therapy shops, where they cut, sew, dye and weave rags into rugs, make dolls' and children's clothes, do embroidery and tatting, and knit.

In many cases, hand work gives an outlet for repressed energy. To many patients, it might well be said, "Your cure lies in your own hands." Some patients write letters, stories or poems. Reading is encouraged, and there are libraries well stocked with books and magazines for the fairly large number of patients who will benefit from their perusal. The *Lakeside News*, a weekly mimeographed sheet, is very popular.

Of course, there are depressed patients and others with delusions, whose interest, for the time being at least, cannot be aroused by work or reading or any other form of occupational therapy. Some of them are helped by shock therapy or the specific treatment of an underlying disease, syphilis for example. There are always a considerable number of deteriorated or senile patients who need only to be made as comfortable as possible.

The possible percentage of cures or of improvement in mental health cannot be secured if the patients are considered merely as groups. They must also be treated as individuals, each having their own mental trends and complexes. Nearly all are benefited to some extent by any special interest shown in them on the part of the staff and attendants.

Beside the psychosomatic treatment, which naturally has a large part to play in the care of patients in a mental hospital, there are certain physical and medical agents which are used to advantage.

Hydrotherapy was not employed to any considerable extent while I was at the hospital, perhaps partly on account of expense and lack of trained personnel, but also, I believe, because it is not as much in vogue as formerly.

Electric shock and insulin shock were given to a rather large number, especially to catatonics and other schizophrenics, but also to manic depressives, and those suffering from melancholia and other affective disorders. The treatment was prescribed and regulated by the superintendent but often administered by the assistant physician. I did not particularly enjoy giving electric shock. It is not pleasant to watch a patient having a severe convulsion. However, the apparatus used is almost foolproof, and to my knowledge there have been no fatalities at the hospital. Fortunately, the patient has no recollection of the experience, and in many cases there is apparent improvement. So far as I know, no one has explained satisfactorily what really happens and there is some question as to the ultimate results. Some patients receive at least two electrical shock treatments a week, for two or three months. Metrazol shock is rarely used, even when safeguarded by curare.

Another form of treatment, which at times causes the physician considerable anxiety but which seems to be quite effective in syphilis of the nervous system, is the production of increased bodily heat by malarial infection which is then controlled by quinine.

In ordinary medical practice, a report of a temperature rise to about 106° would be quite alarming to any physician. It was, therefore, something of a surprise to me to be expected to maintain a patient's temperature at that level for several hours a day for a number of days. Without hyperthermy the prognosis of paresis has always been grave. It is a little more hopeful now.

One might suppose that a state hospital would be a very noisy place. It usually is not. Of course, at times, certain disturbed patients do make quite a racket. But they are not always responsible for weird sounds; radios account for some of them. Self-centered patients are not disturbed too much by the noises others make. Usually if a patient is continually creating a disturbance, he is given a sedative. The doses used and apparently well borne are somewhat larger than those usually given in private practice. Morphine was used much less often than I had expected.

Generally, it was only the agitated patients, who

would exhaust themselves by excessive activity, who required much sedation.

Of course, restraint was also often necessary in such cases, both for the protection of the patient himself and others. The use of low beds, of wooden or metal guards beside the bed, of restraint by sheets or by leather fleece-lined cuffs applied to the wrist or ankle, and finally the dressing of the patient in jackets euphemistically called "camisoles," were measures available. The camisole is a canvas jacket, the sleeves of which are long and closed so that the patient's hands cannot be destructive. It could be applied carelessly and make the patient very uncomfortable. The nurse in charge of each floor is responsible for its proper adjustment.

Restraint of some sort is necessary in the case of any patient with delusions, even if he is not destructive or violent. Otherwise, he would wander about and get lost or come to harm.

The only alternative, and the one which I believe would have to be used if no restraint were permitted, would be to have a sufficient number of nurses and attendants so that the patient was constantly under surveillance.

History taking often threw some light on the reasons for the mental breakdown. We often got an inkling of the causes of the pitiable condition of many of the individuals we saw daily, from their previous records.

Some of the failures are due to inherited weaknesses, but many of them are the result of unfavorable environment and lack of training. This places a heavy responsibility on parents and all who are part of the world of growing children.

Meyer[2] has pointed out the folly of regarding the bodies of patients as somehow separate from their personalities, and not regarding the individual as a social unit.

The world needs as social units persons who have courage, who will face difficulties and run risks. This usually means that they have a moderate amount of good sense, science, philosophy, and/or religion.

They must not be preoccupied with themselves or think that they are the most important individuals in the universe. In other words, they must not take themselves too seriously.

They cannot afford to indulge in the unhealthy emotion of hatred. Other emotions and appetites, necessary and useful in their place, must be kept under reasonable control.

Children trained along these lines are likely to grow up to be normal social units that will harmonize with other social units so that group action may be effective and progressive whether the group be a medical society, a legislature, or a society of nations.

We therefore need more people who understand human nature and its aberrations. We need many more psychiatrists and physicians who use psychosomatic medicine, and we need places where they can be trained.

Mental disease can be studied in our state hospitals. There is a wealth of material there. They could become centers of research and study, adjuncts to the University, and places where generations of interns and postgraduate students could secure thorough and invaluable experience and instruction. Politics should have no place in them. The state can well afford to provide comfortable homes and adequate salaries for even the assistant physicians and their families in order to build up permanent staffs of high quality, who would be stimulated and encouraged to do good work by the presence of interested students. The wages of other employes should be adequate. Antiquated buildings in other state hospitals should be promptly replaced, and overcrowding should be eliminated.

We have, then, near at hand a medical center of which we should be proud and of which even now we could make more use. With some effort on the part of members of the medical profession and other good citizens, it should become one of the great teaching institutions of the Midwest.

CLINICAL-PATHOLOGICAL CONFERENCE

A CURE FOR NEUROGENIC BLADDER

Case Study

O. E. SARFF, M.D.
Duluth, Minnesota

Dr. A. H. Wells: I would like to wager that less than half of the audience know of a fairly recently devised and successful treatment for the paralytic bladder. Any prolonged delay in instituting this proper therapy frequently leads to irreversible changes not amenable to operation.

Case Study

Dr. O. E. Sarff: The patient, a white man, aged thirty, was admitted to the hospital complaining of bilateral flank pain of a dull character. He had had a hematuria for two months associated with some burning, smarting and frequency of urination. He had lost 20 pounds in approximately the last four months. He also stated that as long as he could remember he had had a dripping of urine which kept his clothes continuously soiled. Between normal voidings there was a continual escape of urine. His past history revealed that he had been operated upon at the age of two weeks for spina-bifida. His mother died of tuberculosis.

The physical examination was negative with the exception of tenderness in the region of the navel and bilateral club feet. Laboratory studies of the urine revealed a specific gravity of 1.014, pH 7, albumen 4-plus and microscopically packed fields of red blood cells, pus cells and bacteria. The urine culture had Pseudomonas pyocyaneous and Streptococcus fecalis. The red and white blood cell counts were within normal limits. The blood urea and creatinine were average. An intravenous pyelogram revealed a bilateral hydronephrosis and bilateral hydro-ureter. The patient was running a fever of 100.3°. An indwelling catheter was placed in the bladder and it was lavaged with 1:10,000 zepherin every three hours. The patient received adequate fluids and penicillin, 100,000 units every four hours.

The patient improved symptomatically. On November 27, two weeks after admission, cystoscopic examination revealed a small spastic bladder with marked trabeculation and a chronic type of cystitis. The roentgenogram (Fig. 1) revealed a very small bladder. He was kept on indwelling catheter drainage and bladder irrigations with sulfadiazine and penicillin until the urine cleared of pus, blood and bacteria.

On December 14, a transurethral resection of the bladder neck was performed. An indwelling catheter was removed on the fifth postoperative day. The urine was cloudy at this time. The patient could void as much as 300 c.c. There followed an additional estimated 150 c.c. of involuntary urination. He voided every two hours. On the seventh postoperative day he had a chill with the temperature going to 105°. The catheter was immediately replaced. The temperature dropped several hours later to 101° and the following day it returned to normal. The catheter was again removed on the ninth postoperative day, following which he voided approximately 200 c.c. at a time, every two to three hours. He still had involuntary urination, especially during the night. Because of his mental state, I felt it would be advantageous for him to go home for Christmas and return later.

The patient was readmitted on December 26, afebrile and urinating without difficulty. His fluid output at this time was 1,500 c.c. However, he did have several episodes of urinary incontinence. His urine had a pH 5 with a specific gravity of 1.021, a trace of albumen and 200 pus cells, few bacteria and a few red blood cells per high power field cells. The urine varied between this amount of pus to where there were occasional red blood cells and 50 to 60 cells per high power field.

The patient had a marked intolerance for penicillin, and shortly after the second admission the drug was withdrawn. He immediately became afebrile. He was given streptomycin, 2,000,000 units in divided doses daily.

Because of the rather unsatisfactory results of the previous resection, on January 28 a cystoscopic and cystographic examination was performed. The bladder capacity had increased from approximately 40 c.c. to about 180 c.c. After placing 300 c.c. of media in the bladder, both ureters and the left kidney pelvis filled with the opaque media (Fig. 2). There was a marked destruction of the left kidney. No dye came through this kidney after intervenous injection of indigo-carmen.

On February 10, the bladder neck was again resected and approximately 2.5 grams of tissue were removed. The bladder at this time was markedly improved. There was no reaction following the operation. The catheter was removed on the third day. The patient was instructed to void every two hours. The bladder was at times filled with water, and the patient was instructed to attempt to shut off the flow of urine while voiding.

After several weeks he became entirely continent during the day and had only rare involuntary urinations at night. The patient was discharged with completely clear urine. He had remained dry for a period of about ten days, and his general health had definitely improved. The change in mental status was remarkable.

From the Department of Urology, St. Luke's Hospital, Duluth, Minnesota.

He had taken a new lease on life and was looking forward to doing some sort of work. Because of the status of the left kidney, however, he was asked to return for another check-up.

Fig. 1. Roentgenograph revealing early severe contraction of urinary bladder.

Fig. 2. Roentgenograph revealing increased capacity of urinary bladder and extreme left hydronephrosis and hydro-ureter.

He returned on May 1, free of all symptoms with the exception of some frequency, burning, smarting and at times an urgency which allowed an escape of a small amount of urine. He did not think he had been running a fever. The urine, however, had a marked pyuria and he was again put on streptomycin. After clearing the urine, a retrograde filling study was again done. It had previously revealed a marked destruction of the left kidney with no measurable function. I felt that there was no visible tissue in this kidney and that it was serving as a focus of infection. Therefore a left nephrectomy was accomplished on May 15. The kidney (Fig. 3) had a grade III hydronephrosis. The patient made an entirely successful and smooth convalescence and was discharged on May 31 with complete control of his urine, and the urine was crystal clear.

On December 1, an intravenous pyelogram revealed no changes in the right kidney from the previous examination. A urinalysis revealed at this time only a few pus cells. He had been working steadily and had had complete control of his urine at all times.

Discussion

The past decade has seen a marked revision in treatment of neurogenic bladder dysfunctions. The etiologic factors involving the spinal cord include trauma, congenital anomalies, inflammation, degeneration, and neoplasm. Regardless of origin of the neurogenic bladder, the transurethral treatment is directed to the problem of relieving a spastic bladder and vesicle neck obstruction which does not permit the proper emptying of the bladder.

There have been several excellent classifications, but for practical consideration it is necessary only to divide the conditions into the (1) atonic, and (2) hypertonic type of bladder. The treatment is the same for both groups. The atonic type of bladder is seen in the tabetic and during the first or shock phase immediately following injury. The hypertonic or chronic stage is met with in all long standing cases except the tabetic bladder and is usually seen in from two to six months after the initial injury.

Cystometric examination has not been satisfactory except in determining the type of bladder, while cystoscopic examination reveals not only the type but affords an ample opportunity for studying the vesicle neck as well as the bladder structure. It follows that a competent neurological examination is essential.

During the acute stage, an indwelling catheter with closed drainage, well tolerated, is entirely satisfactory. Bladder infection should be carefully controlled with chemotherapy and irrigations. It is of importance to maintain a good blood electrolyte balance. Great care is to be exercised in the control of decubitus lesions which usually accompany cord trauma.

After the acute stage, transurethral resection is the present choice of therapy. This form of treatment has been extended with gratifying results to include bedridden patients. The rationale is that of removing the vesicle neck obstruction which is due to hypertrophy of the detrussor muscles and fibrosis at the bladder neck. The resection should be carried out in the entire circumference of the vesicle neck and distal to the veru.

Serious bleeding is often encountered if too enthusiastic a resection is carried out. It is far better to accomplish the resection in several stages rather than go too deep in an attempt to remove the entire obstruction. It has been my practice to give the patient a fair trial following the resection before resorting to further procedure. A patient must also be mentally equipped to cooperate, and he must have a desire to do so. Much of the success or failure depends on the careful and close co-operation between the patient and the physician following the surgical procedure.

QUESTION: What are the main symptoms in differential diagnosis?

ANSWER: Symptoms vary, of course. The neurogenic factor is usually known because of the cord lesion. One must be ever on guard for an ectopic ureteral orifice which may cloud the diagnostic picture. The symptoms vary according to the amount of infection and renal involvement. The incontinence is usually not a constant drip as is found in damage to the sphincter, but the urine escapes in spurts intermittently.

QUESTION: What tissue is removed in this type of case?

ANSWER: That again varies. It is usually a mixture of hypertrophy of the detrussor muscles and fibrosis. In the elderly patient one must, in addition, remove varying amounts of prostatic tissue. It is the muscle hypertrophy and fibrosis that forms the "collar" which obstructs.

QUESTION: What is the cause of the bilateral hydronephrosis and hydro-ureter?

ANSWER: Unquestionably the etiological factor is the long-standing bladder neck obstruction. This same type of upper urinary tract destruction is encountered with congenital urethral valves and, in rare instances, long-standing prostatic obstruction. However, the latter is of minor consequence, usually due to the fact that it receives adequate attention.

QUESTION: Were tuberculosis and syphilis ruled out in this case?

ANSWER: Yes. For the sake of brevity, this was not adequately discussed. However, the guinea pig tests were normal and also the blood Wassermann test.

Conclusion

It is not generally known among the profession that urologists have been accomplishing gratifying results in patients suffering from neurogenic bladder dysfunctions. Although immediate treatment is important to prevent upper urinary tract destruction, some cases of many years' duration may be greatly improved.

I have presented a case of a thirty-year-old man, the victim of a congenital lumbar spina-bifida and meningocele, complicated by neurogenic bladder, bilateral hydroureter, bilateral hydronephrosis with marked renal damage to the left kidney. Transurethral resection of the bladder neck and left nephrectomy resulted in a satisfactory physical and mental change in what had been considered a completely incapacitating and hopeless condition of many years' duration.

TEAMWORK IN PUBLIC HEALTH

More effectively than any other approach, medicine and public health can build a conception of common human need, of the single destiny that awaits life on this planet, whether it be good or evil. We are members of one human family, fighting the same enemies of disease and suffering. Only by united effort can we survive, and the field of public health can be a practical demonstration of a new kind of teamwork. It can be a bridge across the gulf that separates this frightened present from a saner and better balanced future. Symbolically and literally, it can bring its healing techniques to a human society that is desperately sick.—RAYMOND B. FOSDICK, Am. J. Pub. Health, Jan., 1948.

Case Report

TUBERCULOSIS OF THE HIP

JACKSON E. UPSHAW, M.D., and WILLIAM H. BICKEL, M.D.
Rochester, Minnesota

A CASE of tuberculosis of the hip which was interesting in the excellent result obtained, as well as the difficulty experienced in diagnosis, is being reported. The fact that this patient, who had proved tuberculous infection of the hip, obtained a spontaneous arrest of the process and maintained almost a complete range of painless motion in the hip is felt by us to be unique.

A perusal of the literature reveals a paucity of cases of tuberculous involvement of the hip in which a good result was obtained in so far as motion was concerned. Hyde[1] stated in 1932: "Adequate motion returns to a tuberculous hip only when the diagnosis is made at the incipiency of the disease and treatment immediately instituted. When such a result is obtained, the diagnosis may justifiably be doubted unless it is supported by incontrovertible bacteriological or pathological proof." This statement is felt by us to be as applicable to cases seen currently as it was in 1932; in view of the rarity of cases of tuberculosis of the hip in which good function is recovered, we report the following case.

Dr. Upshaw is a Fellow in Orthopedic Surgery, Mayo Foundation and Dr. Bickel is in the Section on Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

Report of Case

A Negro boy, four years of age, was admitted to the Mayo Clinic, April 28, 1943, and the following history was obtained: The patient had been well until January, 1943, when following a fall on the left hip as his feet slipped on a waxed floor, a limp developed and he seemed to have some pain in the left hip. After the limp had persisted ten days the boy's mother took him to a physician, who treated him by traction to the left leg for a week and then applied a plaster cast. The cast remained in place some two months and was removed April 20, 1943, one week prior to his coming to Rochester. The patient had walked with a pronounced limp during that week.

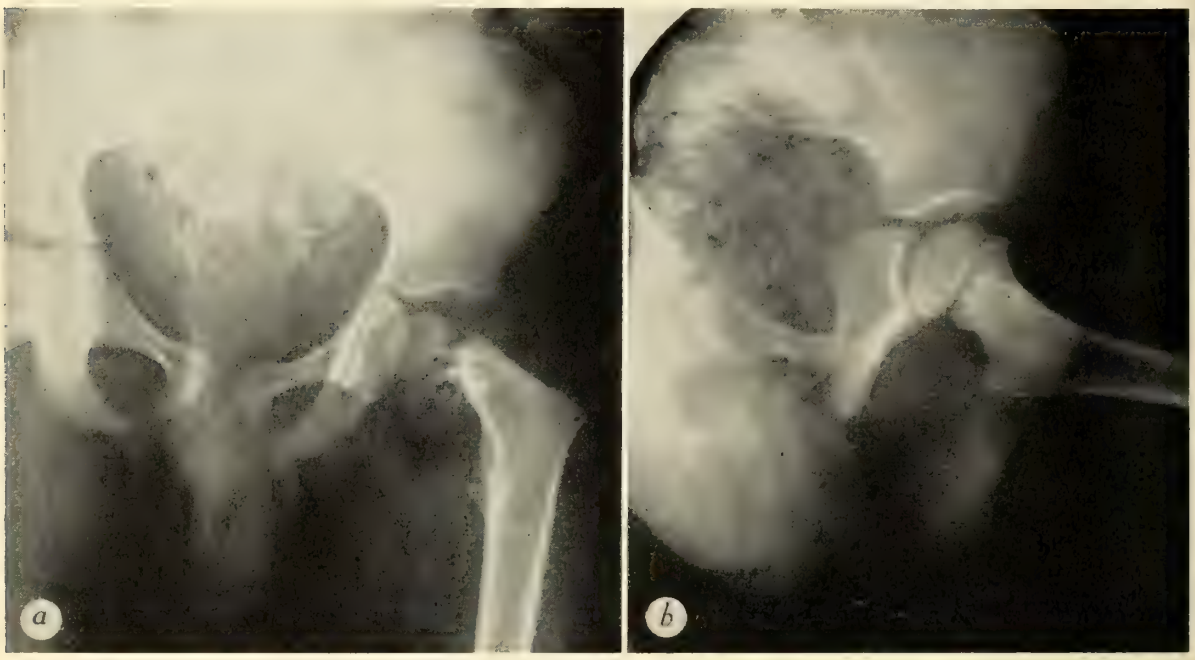

Fig. 1. Left hip on admission April 28, 1943. (a) Anteroposterior view. (b) Lateral view.

Physical examination on admission gave essentially negative results except for findings referable to the left hip. There was slight limitation of flexion and of internal and external rotation. Slight palpable grating was felt in the left hip on motion. There was no tenderness. The legs were equal in length. The Trendelenburg sign was mildly positive on the left and negative on the right. The patient walked with a marked limp.

Roentgenograms (Fig. 1) revealed a peculiar type of destructive lesion of the femoral neck in the epiphyseal region with separation of the capital epiphysis and some fragmentation and erosion of the upper end of the neck. There was some upward displacement of the neck of

the femur with rotation of the femoral head. Roentgenograms of the thorax were negative except for calcified hilar nodes on the left. Routine examinations of blood and urine revealed normal findings, and serologic examination gave negative results.

Although a tuberculous infection of the hip was regarded as a possibility, it was felt that the clinical history and roentgenologic findings were not entirely compatible with a diagnosis of tuberculosis of the hip and that a chondroma or bone dysplasia of the epiphyseal region could not be ruled out without a biopsy. Accordingly, exploration of the left hip was carried out on May 4, 1943. When the lesion in the neck of the femur was approached, thickening of the capsule and soft tissue was seen. When the capsule was opened, some caseous necrotic material was encountered. The cartilage on the head of the femur appeared normal. Specimens of the thickened tissue and necrotic material were sent to the pathologist, who reported tuberculosis. When this report was received, the tissues were closed tightly and a spica plaster cast was applied. The results of subsequent examination of fixed slides of the material taken for biopsy and of the guinea pigs separately inoculated subcutaneously and intraperitoneally with material removed from the hip at operation were positive for tuberculosis.

Treatment consisted of immobilization in a series of double spica plaster casts for fourteen months with the hip in slight flexion, abduction and internal rotation. Following immobilization a walking caliper brace was used for ten months. In September, 1945, two years

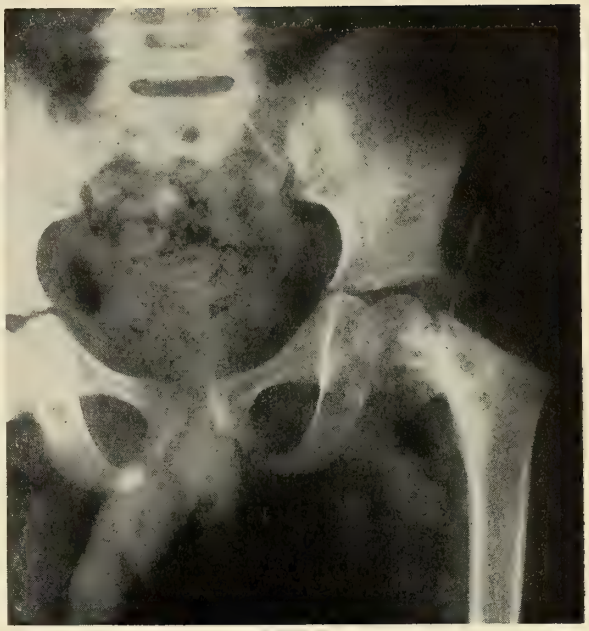

Fig. 2. Anteroposterior view January 15, 1944, after eight months of immobilization in a double spica cast.

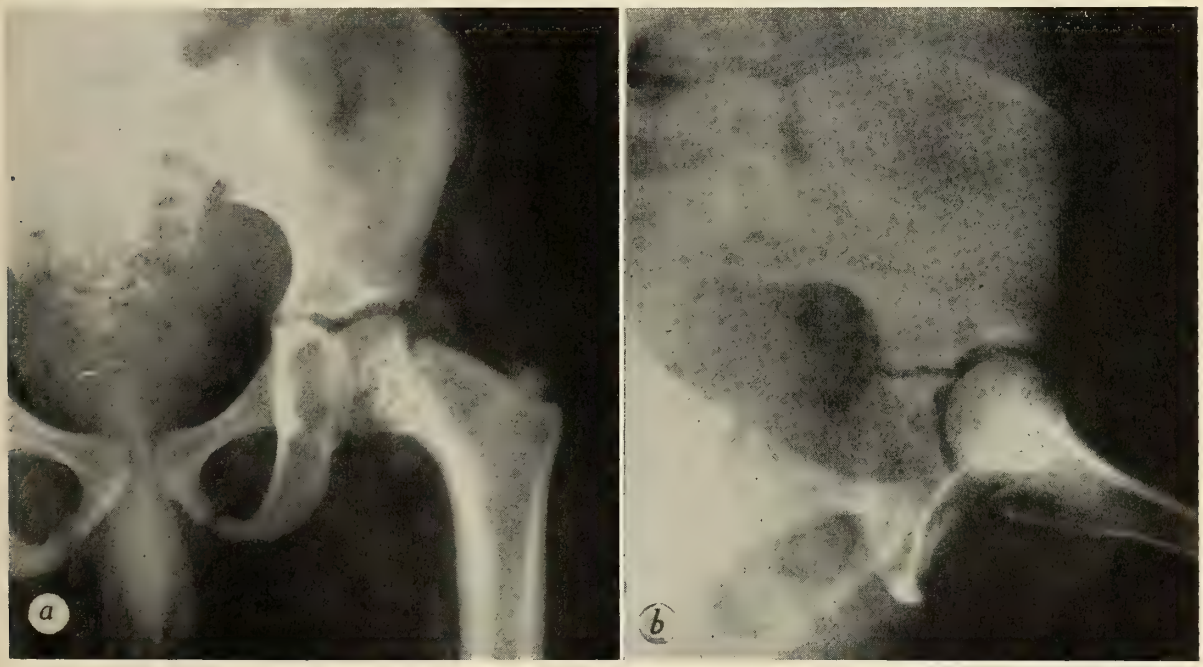

Fig. 3. June 10, 1946, nine months after resumption of normal activity. (a) Anteroposterior view. (b) Lateral view.

and eight months after the onset of symptoms in the hip, the patient was allowed to resume normal activity and start school. Frequent recheck examinations and roentgenograms made during the period of active care revealed steady progress toward healing (Fig. 2) of the bone lesion and a remarkable retention of active motion.

On June 12, 1946, three and a half years after the onset of symptoms, the patient was last seen. At that time almost complete, if not complete, resolution of the tuberculous process was noted in roentgenograms of the hip (Fig. 3). Some osteoporosis of the inferior portion of the head was still present and two cystic regions about the acetabulum were present which, it was felt, would bear watching. Flexion of the hip could be carried out from 180 to 110 degrees. There was slight limitation of internal and external rotation. Other motions of the hip were normal. The patient walked with only a very slight limp. His general health was good and physical examination gave negative results except as noted. He had completed the previous nine months' school term, indulging the rigorous activity of the normal schoolboy, without suffering from any disability from the hip.

History of Medicine In Minnesota

A HISTORY OF MEDICINE IN SCOTT AND CARVER COUNTIES

Scott and Carver Counties were settled in the early fifties, at favorable town sites along the Minnesota River. Thomas A. Holmes, one of the earliest "town site hunters" in the Northwest, came up the river in the spring of 1851 and located the sites of Shakopee and Chaska. Almost immediately Shakopee flourished as a settlement. Dwellings, stores, churches, and a post office had been erected by the spring of 1853 when Scott county was established by the territorial legislature.

Holmes sold the site of Chaska to David Fuller in the spring of 1852 for $1,000. The next year the first settlers, mostly Germans from Saint Paul, arrived. Carver County, together with several other counties, was established by the territorial legislature in 1855. In that year the long stream of immigration began in earnest. The Sioux tribes left Scott and Carver counties, and more safety was afforded the settlers. Country districts became populated after 1857, when town site speculation crashed and settlers turned to farming.

Dr. Frederic N. Ripley was the first physician in Scott County. He came as a trader and land claimer, and did not intend to support himself by his medical practice alone. He spent the winter of 1852-1853 in trade at Shakopee. Failing in that venture, he gave it up in the spring, but continued the practice of medicine there. During the first year, Dr. Finch and Dr. Kinney, both of Saint Paul, made the trip up the river occasionally and attended the sick. Dr. Kinney had a claim shanty at Shakopee, and he must have made several trips up the river to protect it since his claim was vigorously disputed. During the summer of 1853, many of the settlers were ill of fever, and a number of the children died. At such times, many of the settlers vainly attempted to treat themselves. One of the most ill founded "cures" was the placing of powdered sulfur in the stockings as a treatment for the grippe. Dr. John L. Wakefield settled in Shakopee in the spring of 1854. He was a graduate of Yale and had had six years of practice prior to his arrival. He too laid out a claim. He was, in fact, accused of claim jumping. However, he made no permanent enemies since he was a fine doctor and was badly needed in the community.

In the same year, thirty-six-year-old Dr. John Landenberger, settled at Helena, Scott County. He was famous among early sportsmen as the most successful and the most frequent participant in the chase. It was said that he brought home three to seven deer from each day's hunt. Both Dr. Landenberger and Dr. Wakefield practiced in Scott County for many years.

Dr. Charles Lord was another early settler who came to Carver County in 1854. His health had failed, and he believed, as did many others, that the climate of Minnesota would be a favorable change. Incidentally, many consumptives came to Minnesota for the same reason that brought Dr. Lord; and, as a result, the Minnesota death rate was augmented considerably. Dr. Lord staked out a 160-acre claim near Shakopee in the fall of 1854. He farmed during the fifties; and in 1864, upon regaining his health, he moved to Shakopee and practiced medicine there for the next twenty-three years.

The spring of 1855 brought an inrush of immigrants, and with them came cholera. Shakopee was one of the leading river points on the Minnesota at that time, and the disease was brought by boat up the river. In addition to the usual summer fevers there was an epidemic of typhoid. Dr. Josiah S. Weiser and Dr. A. O. Risley came to Shakopee that summer, making a total of four practicing physicians there, so that one or two of them must have been available at all times.

These men were prospectors as well as physicians. Dr. Risley came as a member of the North Western Pioneer Company and made frequent trips around the territory procuring and surveying town sites. Dr. Benedict Lehmann, who came to Carver county in 1856, pushed farther to lay out the village of Helvetia on the Crow River. The hardships of such a life are epitomized in the experience of Shakopee's first physician, Dr. F. N. Ripley. Late in the year 1855 he moved to a town site belonging to him near the source of the Crow River, now the town of Litchfield. He camped there during the winter; in March he and a companion started from Cedar City to Forest City to obtain supplies. Half way there they strayed from the road and wandered for two days in a snow storm. Exhausted, the doctor lay down to die. McLelland, his companion, kept on and at length found an unoccupied cabin, where he spent sixteen days with little food and no fire. He was found, half-starved and badly frozen, by an exploring party and was brought to town. There both his legs were amputated. McLelland surmised that the doctor's remains had been devoured by wolves, as he himself had experienced difficulty in keeping the wolves off while in the cabin. The beautiful lake at Litchfield is named Ripley, presumably for the doctor who first laid out the town.

Amputation of frozen limbs was not uncommon in the experience of the pioneer physician. One account from the *Shakopee Independent* for April, 1856, reads:

> Amputation was performed severing both members slightly above the ankle, the patient meanwhile under the influence of chloroform. The operation was performed by Drs. C. L. Davenport, Wakefield, Weiser, and Leriemondie, and is spoken of as being an exceedingly well executed and delicate surgical operation.

C. L. Davenport, mentioned in the above, came in 1856. He remained but a few months in Shakopee and was a co-partner of Dr. Weiser. Several other physicians settled in Scott County before 1860. Among them was Dr. Phillip M. Williams, a typical Virginian of good breeding in search of adventure or a fortune. He was a gentleman and made friends on all sides, but soon he passed on in search of a larger field. Dr. Salisbury was the first physician in the township of St. Lawrence, Scott County. In addition to the practice of his profession, he taught the first school there. Physicians were among those best fitted for civic duty where schooling was a prerequisite. William A. Griffin, the first resident physician in Carver County, held many public offices. He became the first justice of the peace in the town of Carver, and was also the village president and treasurer. Dr. Weiser served as mayor of Shakopee in 1858.

Weiser's further adventures are deserving of note since his death precipiated one of the major engagements of the Indian war in Dakota, the Battle of Big Mound. In 1862 he was appointed surgeon to the First Regiment of Mounted Rangers, although at the time he was only twenty-nine years old. The following account is based on official records:

> While pursuing a large body of Indians in the summer of 1863, the troops under General Sibley were halted at Big Mound, North Dakota. Through the interchange of communications between the scouts, the Indians expressed a wish to have a conference with General Sibley. He having been warned of danger declined. Dr. Weiser, however, went among the Indians,

many of whom he knew, and returned to camp saying they only wanted peace. He shortly returned to the top of Big Mound with two or three other persons and was almost immediately shot and killed. His companions escaped by hard riding and by the bad marksmanship of the Indians. As soon as the killing of Dr. Weiser was known, General Sibley ordered the First Battalion to attack the Indians, which they did, accompanied by some companies of the Sixth and Tenth infantry regiments. A fearful thunder storm came on during the attack and lightning killed one cavalryman, but the Sioux were routed; and although it was against Sibley's orders, a number of rangers brought back scalps in revenge for Dr. Weiser's death.*

Difficulties with the Indians touched the lives of many of our pioneer physicians. At the time of the Indian outbreak in 1862, Dr. John L. Wakefield of Shakopee was physician at the Yellow Medicine Indian Agency. The doctor escaped but the members of his family were captured by the Indians and held for six weeks until rescued by the troops.

The pioneer physician endured more than the usual hardships of an early settler. The cold winters were hard for everyone, and the roads were always difficult to travel; but it was the physician's duty to go out at any time, whatever the weather, and to travel for hours on horseback over nearly impassable trails with all the speed he and the horse could endure. Illustrative of their hardships is a quotation from the diary of an old settler regarding Dr. Southworth, who established a practice at Belle Plaine during the middle fifties:

> Old Dr. Southworth is dead. He had so much practice that it wore him right out.

Dr. John A. Macdonald who settled in the vicinity of Chaska about 1859, was a pioneer physician who became prominent. In the year 1864 a severe epidemic of smallpox raged in both Carver and Scott Counties, and Dr. Macdonald did much to relieve the sufferers. He wrote an article published in the *Valley Herald* (April, 1864) for the purpose of calling the people's attention to sanitary and preventive measures. It read:

> The painful fact that smallpox in some of its various grades, from that of varioloid to that of the confirmed confluent, has broken out in this vicinity is now no longer a matter of doubt. . . .

The following were, in brief, his recommendations:

> (1) Not to give way to unnecessary fears, for by doing so they greatly affect the nervous system, (2) cleanliness of person, clothing, and dwellings; no direct communication to be held with persons affected, (3) for persons believing themselves attacked not to be swallowing by the wholesale boxes of cathartic pills, (4) children above the age of six months should be immediately vaccinated. I am sorry that much apathy is shown by parents in this matter. (5) re-vaccination, especially after seven or eight years have elapsed since the first vaccination, (6) removal of valuable articles of wearing apparel, extra bed clothing, et cetera, to a distance from the affected room where they may be freely exposed to a current of pure air. (This to be done on the first appearance of the disease.) This precaution will prevent clothing from communicating the disease to others.

The epidemic was almost immediately checked at Chaska. The deaths were attributed more to want of timely treatment and imprudent exposure than to the violence of the disease. There were a few cases at Chanhassen and several mild ones at Carver during the month of April. At the same time, smallpox appeared at Shakopee. An early settler wrote in his diary:†

*Quoted in somewhat abbreviated form from the *Shakopee Argus Tribune*, December 20, 1928.

†Diary of D. M. Storer, published in the *Scott County Argus* in 1899 under the title of "Pioneer Days—A Daily Résumè of Early Scenes and Events in the History of Shakopee."

April 1-4. There is a good deal of excitement in town about the smallpox. There are two cases of it and some of the people had just as leave spread it as not.
April 12-14. Our boy is quite sick from the effects of vaccination.
July 5-9. The smallpox is in town again, there being two cases of it.

In August a number of cases of smallpox appeared in Carver County some ten miles from the river. Dr. Macdonald reported that five children in a German family died from its effects because he was called too late to render them any assistance. The disease seemed to be of a virulent form. Several cases of a lighter type appeared at that time within two miles of Chaska. Many people in both counties had the disease in a mild form throughout the following winter. The citizens of Chaska became alarmed again toward spring, and many parents took their children out of school. No quarantine regulations existed, no means of isolation was provided, and there was no board of health. As was anticipated, the disease reached alarming proportions in several localities as spring approached. In May of 1865 the towns of Sand Creek and Helena had twelve to fifteen deaths. In the spring of 1865, Chaska's only physician, Dr. Macdonald, joined the Second Minnesota Cavalry as First Assistant Surgeon. That left Chaska, a town of between 800 and 900 persons, without a resident physician.

During the next few years, little sickness was reported either in Chaska or in Carver. A number of physicians tried to establish practices in each town, but, attracting few patients, they moved on. Residents of Chaska called on Dr. Griffin of Carver or Dr. Wakefield of Shakopee when need arose. Smallpox recurred here and there, noticeably in January, 1867. Measles became prevalent at Waconia in 1868. Except for a few of those patients there was not much practice for a new physician in the locality.

Shakopee was visited by scarlet fever during the first years of the sixties. A severe form of the disease appeared in the summer of 1860 and spread rapidly. A number of children died during the summer, and the epidemic continued into October. In the next year several more scarlet fever deaths occurred, but the disease affected only the children.

It was not until 1870 that Carver County appointed a county physician, while Scott County appointed one about fifteen years later. Until then the county poor funds had covered whatever bills were incurred when the county commissioners called for medical care of paupers. The county physician had no responsibility or authority in the prevention or control of disease; it was for the purpose of disease control and prevention that the towns bestirred themselves, and boards of health in the larger towns were organized about 1872. But it was not for a decade or more that physicians gained control of the boards. Smaller communities appointed temporary health officers during epidemics, usually at the command of the state board of health.

A series of violent epidemics visited both Carver and Scott Counties in the first years of the seventies. Diphtheria, which had not been extensive in previous years, became a matter of serious concern during the fall and winter of 1874. Belle Plaine and Chaska felt it severely, and there were many deaths.

In December, 1870, there seemed to be more illness in Carver County than at any other time, as recalled by some of the residents. Typhoid and scarlet fever were most common. Dr. E. H. Lewis had just arrived in Carver, and the rush of patients gave him a running start toward popularity and success. The doctor at Chaska, as well, was kept busy since this community also had a great many cases of scarlet fever. It was reported that scarlet fever still raged in Carver County in January, 1871, especially at Carver. Dr. Lewis had over a dozen cases in the first week of January, counting only those of the Swedish settlement there. Several children died

of the disease at Shakopee in December, 1870. The following year there were sixteen scarlet fever deaths and eleven typhoid deaths in Scott County out of a population of 11,000.

Scarlet fever had barely run its course by 1872, when an epidemic of smallpox again struck the Minnesota valley. Early in 1870 it had prevailed in the neighborhood of Young America, in Carver County. Six or seven cases appeared there during March, and most of the people were vaccinated. The cases at Young America, however, appeared to be an isolated forerunner to the epidemic of 1872. It broke out first at Carver, and Dr. Lewis reported a dozen cases about a mile from town in December, 1871. By January 4 the *Chaska Valley Herald* announced that most of the persons in the county had been vaccinated. Hancock town must have been an exception because several new cases appeared there the next week. Dr. Lewis visited Hancock and vaccinated seventy-nine persons in one day. More cases appeared throughout the county; several victims died at Laketown and at Carver during January. In the first month of the epidemic, steps were taken to prevent the spread of the disease at Chaska. It was resolved by the village board that:

The president appoint a committee of three from the Board to act in conjunction with the Board of Supervisors in making such regulations as they may see fit to prevent the spread of smallpox, and that they are also impowered to hire such persons and expend such moneys as they may find necessary to carry out this resolution.

The president then appointed a committee of three as a board of health, and another resolution was adopted which read as follows:

Resolved: That no funeral procession where the diseased died of smallpox shall be allowed to pass through the principal streets of the village of Chaska and the Board authorizes the Committee appointed above to see that this resolution is enforced.

A third resolution read:

Resolved: That all physicians practicing within the limits of the Incorporated Village of Chaska shall notify the president, Hon. F. E. DuToit, of all cases of smallpox immediately after finding the same and failing to do so they shall be fined in the sum of $25 for each and every offense.

The following was also adopted:

Resolved: That any and all persons having cases of smallpox within their families are hereby prohibited from coming into the Village of Chaska on par and penalty of $25 for each and every offense.

Several residents of the town contracted the disease, and many others were exposed. More regulations were made by the board of health, in the first week of February, as follows:

I. That all persons sick or connected with families sick with smallpox shall remain confined within their own houses until cured of the same and for a further period of not less than two weeks.

II. That all persons who may have intercourse with persons having smallpox either in or outside of Chaska shall be subject to the same restrictions as specified above for those in whose families the disease is found.

III. No children belonging to or residing with any family having a case of smallpox in their house, shall be allowed to attend any of the public schools of said place.

Any person violating an order of the Board of Health is subject to a fine of $100 or imprisonment for three months. A strict compliance with this law will be enforced.

The first case in Scott County appeared at Shakopee during the first week of January. A German woman coming from Europe had been exposed to smallpox while passing through New York. As soon as it became known that she had the disease, the city council took charge of the premises where she was stopping. The council then issued an ordinance allowing the city to take complete charge of cases of contagious disease within the city. It also provided "that the Committee on Health of the City of Shakopee should provide a place of reception or hospital for the sick when a disease dangerous to the public health breaks out in the city." The usual type of quarantine regulations were stated and also "that the committee on Health shall see that the provisions of this ordinance are strictly complied with." Violation penalties were not to exceed $25 fine or thirty days in jail. Many of the citizens were vaccinated, and no other cases appeared in Shakopee.

Later in the month of January the disease broke out at Belle Plaine. It was thought to have been brought from Carver, a short distance across the valley. Some fifteen cases appeared in five families there, and several deaths resulted.

Sand Creek appointed a board of health about February 1 and took steps to prevent the spread of smallpox. Only one case was known in the town, but others had been exposed. At Jordan, a child became ill of smallpox, and the town adopted regulatory measures immediately. The board of health reported that all the school children of Jordan had been vaccinated "except one whose father had not sufficient wisdom to understand its utility." The trustees closed the school until the immediate danger was past. Other than the one mentioned, no further cases appeared at Jordan. After February the danger was over. Belle Plaine alone continued to suffer. Scarlet fever still lingered there early in the year, and a new outbreak of smallpox occurred near there in August.

In the year 1872 there were about ten physicians in Scott County, two or three residing at Shakopee, three at Jordan, two at New Prague, one at Belle Plaine, and one at Helena. Carver County had three physicians at Carver, two at Chaska, and others at Watertown, Hancock, Waconia, and Young America. This averaged, roughly, one physician for every 1,400 people for each county. Several villages of 1,200 or more had no physicians. The practice of many of these men covered hundreds of square miles, and they traveled from place to place by wagon and team. Naturally the doctor who owned the best and fastest horse got the most calls. In this district, crossing the river was particularly hazardous. Dr. Lewis of Carver lost a fine horse while crossing the ferry. After getting on the boat, his horse became frightened and jumped into the river, dragging the buggy with him. The doctor lost a valuable case of surgical instruments as well as his horse. The experience of Dr. C. S. Stoddard, who hung out his first shingle at Shakopee in March, 1874, is related as follows:**

> Dr. Wakefield, an old and much beloved physician had died but a few months before and there was a vacancy in the professional ranks. . . . The morning after my arrival I called upon Dr. Charles Lord, the only physician then residing in the place. . . . My second patient was an old lady living six miles east of Shakopee near Bloomington ferry. Mike Ryan took me out with his own team and sleigh late in the afternoon, during a snow storm, promising to surely bring me back the same evening. But before we were ready to return a terrible blizzard came on, and although we had started well on our return trip we found it utterly impossible to face the storm, the horses absolutely refused to go, and we returned to the house to wait till morning. . . . The storm increased, continuing two days and nights. . . . While awaiting for the storm to abate, my services were called into requisition in a neighbor's family, and now, after an experience of 26 years, I am ready to declare that I have never met with so serious a case in all its symptoms and consequences. Of course, I was unprepared for the emergency without instruments or medicine, and felt like a man forced into battle with his hands tied behind him. . . .

**Dr. C. S. Stoddard, "Looking Backward," published in the *Scott County Argus*, March, 1900.

Still I did all I could under the circumstances and I was left in the condition of the young doctor of whom I have heard, who upon being asked how he was succeeding with his first case of obstetrics, replied, "Very well. I have lost the mother and child, but by skillful attention I hope to pull the old man through."

Upon my return to Shakopee on Monday, we met the funeral procession of my first patient who had died during my enforced idleness.

. . . It was really quite a discouraging start for a young physician whose diploma was scarcely dry. . .

I was occupied with patients from the very first . . . looking backward now from my present standpoint of experience, I am led to wonder at the very generous patronage that was accorded me. . .

. . . There was no bridge at Shakopee at that time and we depended upon the ferries in summer and the ice in winter. One of these called the "upper ferry" was on the road leading to Chaska and owned by Ed Bass, while the lower ferry was on the road to Eden Prairie and was under the management of Mr. Wilcox, when he was not too sound asleep to be awakened by the long calls and mental cursings of the doctor anxious to reach his suffering patient on the other side.

Dr. Stoddard had some difficulty with German patients as he could not speak German, but he soon learned enough to get along. Continuing, in his own words, with the story of his early difficulties:

A son of Mr. Rivers of Eden Prairie had shot himself and I was summoned in great haste to his relief. Mr. R. drove the team and I was kept uncomfortably busy trying to stay in the wagon, expecting to be bounced out at every chuck hole, and there were many of these, dark and deep, in the old road which crossed the lower ferry and the bottom lands which lay beyond.

Another interesting phase of the life of the pioneer physician is brought out in Stoddard's mention of an exchange of services between a doctor and a blacksmith. The blacksmith, who had just married, offered to do all of Dr. Stoddard's smithing for a year if Stoddard would take care of his medical needs for the same period. The agreement was made, and at the end of the year there proved to be a difference of only fifteen cents in their accounts. Storer's diary mentions the same kind of arrangement. A town lot was given in payment to Dr. Weiser by the writer himself for medical services during a period of illness.

Strange cases confronted the doctor of pioneer days. Dr. Macdonald was once called upon to stitch up a horse's tongue which had been nearly cut off. Another account tells of a man who was gored by an elk. Burns from boiling water, and injuries to arms and legs caught in farm machinery were common accidents.

Quacks and "cures" were readily believed. It may be noted that during the 1870's the small town newspaper encouraged the acceptance of both. During the summer of 1877 two quacks, who claimed to be cancer specialists, came to Shakopee. They would mislead their patients who came to them with various cancers by first pretending to extract the cancer and then exhibiting to the patient various small animals, dead or alive. They made good profits and disappeared before those who had been "relieved" of toads, snakes and such, became dissatisfied.

Dr. Jacob Haas, of Chaska, a man of questionable reputation, was appointed county physician in 1874.†† All the doctors in the county, eight in number, had applied for the office of county physician, and the citizens of the town were surprised, disgusted, and somewhat amused. (Dr. Haas had offered to accept a salary of $250 instead of the customary $450 per year.) Immediately the Carver representative of the *Valley Herald* pointed out that the entire community hoped "the Board of

††He was not recognized by the members of the medical fraternity of the county or state as a physician, nor did he belong to any school of medicine. Furthermore, he was known to spend a large part of his money in the saloons while his wife and invalid child suffered in want. Nevertheless, his practice was said to be very large.

County Commissioners would have self-respect enough to reconsider their action and fill the place by a respectable physician." He mentioned also that Drs. Lewis, Grant, and Griffin belonged in the latter classification. A battle ensued on the printed page, with one issue of the paper publishing the invectives of the Carver correspondent and the next a mild defense from those of the county commissioners who had voted for Haas. It appeared that a resolution had been introduced immediately after Haas was appointed, saying "that the salary of the County Physician be drawn by an agent to be appointed by this Board whose duty it shall be to pay the same to his family (the Physician's) from time to time as in his judgment their necessity may require." Three of the five county commissioners were Germans and had voted for one of their own countrymen regardless of their civic responsibility. At last the situation was remedied by the appointment of reputable deputy physicians for certain districts, thus limiting Haas' responsibility. The next year a new plan, previously suggested by Dr. Lewis, was put into effect. Each commissioner had the privilege of calling on any doctor he chose to attend the poor residing in his district, at a certain rate per mile (about 25 cents). Medicines were furnished. Evidently extra amounts were paid for surgical operations or special treatments.

Many small or local epidemics struck Carver and Scott Counties during the last quarter of the nineteenth century. Among the diseases common to children there were measles, cholera infantum, whooping cough, chicken-pox, and spinal meningitis. Influenza, or the so-called *"la grippe,"* appeared frequently in isolated cases, and every few years in epidemic form, most noticeably during the nineties. Comparatively few cases were fatal, however. Lung fever was not uncommon, and many fevers and inflammations, inexpertly diagnosed, were given as the cause for deaths. Scarlet fever, smallpox, and typhoid continued their ravages from time to time.

By far the most fearful and frequent of epidemics was diphtheria. In 1878 it prevailed in several parts of Scott County, as well as in other parts of the state. In 1880 the *Shakopee Argus* published a circular from the state board of health giving the causes and means of preventing or checking diphtheria, since it continued to linger in that locality. The fall of 1881 brought an epidemic of the worst type, centering at Shakopee, which was then a town of around 2,000. Twelve persons died there of diphtheria before the New Year, and many more were affected. The committee on health was ordered to act according to Ordinance No. 12, made at the time of the 1872 smallpox epidemic. The committee investigated all cases suspected of being diphtheria and ascertained whether or not the patient suffered from that disease. They were allowed to employ two physicians. Permission was also given the city council "to cause each patient to be removed to a hospital to be established for that purpose, and to cause the premises where the sickness occurred to be thoroughly disinfected, or else to cause a red flag to be displayed at the front door of the house where such sick persons might be; and to adopt such quarantine regulations as might be necessary to prevent communication between the inmates of such house and the other inhabitants of the city." It was further resolved that all cases of suspected diphtheria were to be reported to the committee on health.

(To be continued in the May issue)

President's Letter

CANCER REMAINS MAJOR CHALLENGE

Throughout the month of April, we physicians rededicate ourselves to an important public service by joining in the observance of National Cancer Control Month. The physician can give direction and purpose to the cancer fight—he is the vital link in the chain by which it is hoped one day to subdue cancer and prevent it from further menacing human life.

There are three lines of defense against cancer. First, the patient; second, the practicing physician; and, third, the specialist. Like the corners of a triangle or the legs of a tripod, each one is as important as the other two; without one the others are useless, incomplete, ineffective.

The patient himself is mentioned first because it is he who must learn to know the danger signals of cancer and seek help when they appear. To strengthen this defense, we need intelligent education on cancer to counteract the fear and dread and the false modesty, which, especially for women, so often proves an ally of death. We physicians must help in this effort to educate the people; and we can help by cultivating to an even greater degree a friendly, sympathetic attitude and by being the kind of doctor that a timid, distressed person will turn to and find reassurance. The job of educating the public on cancer is indeed a complicated one. The symptoms of cancer are intimate, personal; yet they must be presented impersonally. Confidence must be built up in the mind of the public; yet false hopes must not be raised.

Because the practicing physician is placed second on our list of cancer defenses, it does not follow that he is any the less important. In reality, he is right on the firing line. He is the one to whom the patient brings his symptoms to be interpreted. Thus a heavy responsibility rests upon the medical profession to spearhead the attack on cancer. Even though health education in cancer is making people "cancer conscious," a patient cannot diagnose or cure his own cancer. Cancer patients are oftentimes saved or lost, depending upon the practicing physician's knowledge and ability to observe. The family doctor must read the signs and take appropriate action, or refer the patient to someone who can.

The third line of action against cancer—the surgeon—holds the key to whatever remedy is possible. He, together with the pathologist and the radiologist, provides the best line of offense to actually eradicate cancer from the human body. No matter how alert the patient and the doctor may have been, without the technical skill of this third unit any cancer case is lost.

Cancer control today is far from the hopeless problem that it was just a few years ago. There is reason to take heart and renew efforts in all phases of the cancer fight. We are seeing results in our cancer education; astounding progress is noted in the field of research considering the baffling nature of cancer. The sad fact is that cancer research needs MORE financial support and MORE trained workers than it now commands. More material aid to the cancer laboratory would produce even bigger life-saving dividends.

Recent trends indicate that cancer is just beginning to come under control. Real progress is being made in reduction of deaths, particularly among women. Education has played some part, but a number of other factors—largely the result of milestones attained through laboratory and clinical investigation—are also at work. Two notable examples are reduction in the number of birth injuries that go uncorrected, which is reducing cancer of the cervix, and better mouth hygiene which is cutting down cancers of the mouth.

It is only reasonable to believe that even more significant progress will be attained by advances in medical and surgical treatment with achievement of more adequate financial support. Cancer control, indeed, remains a foremost challenge, both to the medical profession and to intelligent laymen.

REBATES TO OCULISTS

THE publication of the names of oculists cited by the Federal Government in its price fixing suit, which appeared in the press February 15, came as a surprise to the profession in general. The average physician had no idea that the practice of accepting rebates from opticians by oculists was as widespread as the citation claimed. The citation does not establish guilt, although it must be admitted that where there is smoke, usually there is fire.

The unpleasant situation involves two questions —one of professional ethics and the other of legal liability.

If an oculist charges his patient a fee for refraction and accepts a rebate from the optician who supplies the glasses, there can be no question but what he is guilty of a breach of medical ethics, essentially fee splitting. This practice has been repeatedly declared unethical by the organized profession, and the apparent widespread practice and attendant publicity to the detriment of the medical profession as a whole has caused general resentment among its members.

Whether the acceptance of rebates by oculists subjects them to legal action is a matter of law about which we would not attempt to express an opinion. The Federal Government contends that the oculists and optical firms are guilty of conspiracy to fix the price of glasses in violation of the Sherman anti-trust act. Whether an actual conspiracy can be proven in the forthcoming trial remains to be seen.

The purchase of a pair of glasses after receiving a prescription from an oculist would seem to be a simple matter. It apparently is not so simple, and the way the glasses are supplied varies greatly. Some oculists depend on the optical house to fill the prescription and fit the glasses, and he checks the correctness of the lenses supplied. Some oculists have to send out of town for the filling of their prescriptions. They must fit the glasses and assume the risk of breakage in so doing as well as spend more time on the fitting. A group of physicians or an oculist sometimes hires an optician's services and thus makes a profit over and above his fee for refraction. Or an oculist may conceivably own stock in an optical shop. The question of ethics may thus be rather involved.

If, as the Government contends, the optical houses are making rebates to oculists as high as 50 per cent of the cost of glasses, the price of glasses is considerably higher than it should be. The usual effect of competition is to maintain the price of an article at a level which provides a reasonable profit. The only competition which would seem to exist in the sale of glasses would be in the percentage of rebates made to the oculists. The Government will doubtless try to prove that such a high price for glasses could be maintained only by a monopoly in the supply of materials that go to make up a pair of glasses on the part of two large optical houses.

The supplying of glasses to the public is obviously in a very unsatisfactory condition and requires correction. If the prospective trial will result in the clearing of the practice, with a resulting reduction in the price of glasses to a proper level and the entire elimination of rebates, it will be an outcome to be highly desired. We trust that the trial will not be long postponed for the sinister purpose of keeping the unfortunate picture in the public eye for political purposes. The sooner the air is cleared by the establishment of guilt or innocence, the better.

PROPYLTHIOURACIL

THE value of propylthiouracil in the treatment of hyperthyroidism has been established. Although more toxic than thiouracil on a weight basis, the smaller dose of propylthiouracil required to establish a normal basal metabolism is much less likely to produce toxic symptoms, and has a more prolonged effect. The action of both drugs is in the prevention of the utilization of iodine by the thyroid gland.

Propylthiouracil should be given in 50 mg. doses every eight hours initially in the more

severe cases of hyperthyroidism and only twice a day in milder cases. As the patient improves, the dosage is decreased and 25 to 50 mg. daily is usually sufficient to maintain a restored normal basal metabolism.

While it is possible that the use of propylthiouracil may produce permanent remissions in some cases, its main usefulness is in the preparation of individuals with hyperthyroidism for operation. After the basal metabolism has been reduced to the neighborhood of plus 20, iodine in the form of Lugol's solution should be added and continued for two or three weeks before operation. Some administer iodine with the propylthiouracil from the beginning of treatment. Iodine fosters the involution of the gland which results in less bleeding at operation.

Although propylthiouracil has proven its great value in the preparation of hyperthyroid patients for operation and may prove, as time goes on, to be of even greater value in obviating the need for operation in a larger percentage of individuals, it should be remembered that occasionally toxic manifestations in the form of leukopenia or even agranulocytosis, fever or dermatitis does result. Periodic checks of the blood picture should, therefore, be made, and patients receiving this medication should be warned to report the occurrence of sore throat, fever or dermatitis at once.

RETROGRESSION IN MEDICAL ADVERTISING

MOST physicians of today cannot go back in memory to the days when anyone could advertise almost anything in a medical journal irrespective of its intrinsic scientific value. The practicing physician had no way of feeling certain that a remedy advertised in any medical journal had proven scientific value.

The situation became so bad that the leaders in the American Medical Association realized that something must be done to clean up medical advertising. In 1905 the Council on Pharmacy and Chemistry was established, and outstanding members of the medical and allied professions, for the most part associated with medical schools were asked and consented to serve on the Council. The Council's unbiased opinions, from a clinical and laboratory standpoint, on the usefulness of remedies were to be and have been the basis of the Council's approval or disapproval. The A.M.A., by action of its House of Delegates, deleted many advertisements from its medical publications, taking a considerable financial loss and has since restricted its advertisements to Council-accepted articles.

In 1912, the Board of Trustees established the Cooperative Medical Advertising Bureau for the benefit of the state medical journals. Its function was and is to procure advertisements for the state journals, and members of the Bureau in turn agreed to limit their advertisements to Council-accepted products. Certain leeway was allowed publication committees of the state journals in the acceptance of local products. The existence of the Bureau has been a great source of economy for all the member journals and has resulted in the maintenance of high advertising standards in those journals. MINNESOTA MEDICINE has been a member of the Bureau since it began publication. The *Illinois Medical Journal* has never been a member of the Bureau, and the *New York State Journal of Medicine,* while agreeing for a brief period to accept only Council-approved articles, has for a period of years accepted unapproved advertising.

It is to be regretted that recently the *Rhode Island Medical Journal* and *California Medicine* have strayed from the fold and have left the Cooperative Medical Advertising Bureau. Recent issues of *California Medicine* have contained unapproved advertisements. This is obviously a step backward, in refutation of the Council on Pharmacy and Chemistry, taken for revenue only. This lack of co-operation on the part of these four journals affects all the other state journals financially and lowers the status of medical advertising in general. The House of Delegates of these four states could, of course, bring their journals into the Bureau if they so wished, and should be urged to do so.

PUBLIC DEMAND FOR SERVICE AT NIGHT

The American Medical Association calls on county medical societies to meet the public demand for emergency medical service at night.

"From many sections of the United States," says an editorial in a recent (March 6) issue of *The Journal of The American Medical Association,* "complaints have come lately that persons who have called physicians late at night have been unable to secure attendance from either those whom they considered their family physicians or from specialists or, indeed, from any physician."

The American Medical Association says that large county medical societies or urban groups should maintain a physicians' telephone exchange which would take the responsibility for locating physicians if response is not made to the ringing of the telephone in the home or in the office.

The solution is simple and practical, requiring only a minimum of community organization. A number of county medical societies already maintain a physicians' telephone exchange where doctors' calls may be received and doctors located if their office or home telephones do not respond. Such an exchange can be utilized as at night or on holidays, simply by furnishing the exchange with a list of physicians who are able and willing to make night calls. Such physicians would probably include the younger general practitioners, newcomers to the community, and others in general practice. If such a roster were available, and its availability widely publicized, night calls for medical service would soon gravitate to this center and the patient would be assured the services of a physician.

Under such a system the necessity for calling many doctors would be eliminated. Two calls at most would be necessary. Where there is no physicians' telephone service, it might be possible to have the hospitals cooperate by handling such night calls.

The Medical Society of the District of Columbia and the Milwaukee County Medical Society have found such a plan practical, as have a number of other societies.

By this simple and practical expedient, which is doubtless in effect in modified form in a number of communities, the sick can be served and the medical profession can redeem its pledge of unselfish public service.

It is highly important that where such arrangements exist they be brought to the attention of the lay people in the community through appropriate public channels, not once but repeatedly, to keep the shifting populations well informed.

Few problems in the field of medical service have aroused so much public discussion. Whether resentment against physicians is justified or not, it does harm. The solution for this problem is so eminently simple and would reflect so favorably upon physician-patient relationships that medical societies everywhere are urged to give it serious consideration immediately.

MINNESOTA DEPARTMENT OF HEALTH

Public health nurses and nursing advisory committees throughout Minnesota will join with others throughout the nation in observing Public Health Nursing Week, April 11 to 17. The theme of Public Health Nursing Week this year is "Help your public health nurse help your community."

The present status of public health nursing services in the state shows considerable improvement over the situation a year ago, says Miss Ann S. Nyquist, director of the Division of Public Health Nursing, Minnesota Department of Health. The State Legislature in March, 1947, passed an act subsidizing public health nursing by allowing $1,500 a year from state funds to assist any county in establishing or extending public health nursing services.

During the past year, eleven Minnesota counties have established public health nursing services and eight counties have employed additional nurses. There are now 464 public health nurses in Minnesota, about equally divided between the large cities and the rural areas. Fifty counties now have generalized public health nursing services. Thirteen counties that have set up provisions for public health nursing services report vacancies, and there are still twenty-four counties that have no rural nursing service.

In the three large cities of the state, there is a ratio of one public health nurse to every 3,622 people. This is a very favorable ratio, according to the standards of the American Public Health Association, which recommends at least one nurse to every 5,000 people. In the rural areas of Minnesota, however, one nurse must serve, on the average, 11,013 people. An effort is now being made to train more nurses for work in rural communities, both in hospitals and in public health work. State licensing of practical nurses is also likely to improve the situation somewhat in the rural areas. Already 450 Minnesota women have taken examinations for licensing as practical nurses.

MINNESOTA NURSES ASSOCIATION

The need for students to fill the classes of Minnesota's schools of nursing is of vital importance to every citizen—particularly to members of the medical profession and to hospital administrators.

The Minnesota Nurses' Association has been carrying on a recruiting program for several months, but despite this effort students are still needed for spring classes in both professional and practical schools of nursing. At least 1,500 students will be needed to fill the fall classes, always the largest.

The U. S. Department of Labor estimates that between 500,000 and 600,000 practicing professional nurses will be needed to fill the demand by 1960. This makes the enrolling of students in our schools of nursing a long-range and important question.

In its campaign to interest qualified young women in the profession of nursing, the association has emphasized the following points, and they are factors with which everyone interested in the nursing situation should be acquainted.

More nurses are needed because:

1. The public is demanding not only more but more specialized nursing care.
2. There are more hospital beds today than ever before in the history of the country.
3. An extensive hospital building plan is under way and young women will be needed to staff these institutions.
4. The public health program is growing by leaps and bounds and more nurses are needed in this field.

Thus it is obvious that after a young woman finishes her education in nursing there will be plenty of vocational opportunities for her for years to come.

Nursing offers a greater variety of jobs than any

other profession. A young woman may choose to be a general staff nurse in a hospital, a supervisor, an operating room nurse, a teacher of nursing, a school nurse, a country nurse or an industrial nurse, or an office nurse. There are many more sections of the broad field of nursing also.

Today schools of nursing offer one-year courses in practical nursing and children's nursing.

Not only are the educational opportunities flexible but many schools have scholarship funds and loan funds to help a qualified student receive her nursing education.

Mrs. Dolores Colesworthy of Minneapolis is enrollment chairman of the Minnesota Nurses' Association. She suggests that anyone wishing more information about educational and vocational opportunities in nursing make inquiries at the Association's office, 2642 University Avenue, Saint Paul 4, where all the facts about it have been collected.

PRACTICAL NURSE LICENSURE IN MINNESOTA

To carry out the law relating to licensure of practical nurses and accreditation of schools of practical nursing, Governor Luther Youngdahl appointed three additional members to the State Board of Examiners of Nurses to serve for the purposes of this act only. These persons were Dr. Phillip F. Eckman of Duluth, Miss Alice Barlow, L.P.N., on nursing staff at Minnesota Soldiers' Home, Minneapolis, and Miss Dina Bremness, R.N., superintendent, Glenwood Community Hospital. Their appointments became effective as of August 1, 1947, and since that time, this augmented board has had several meetings at which policies and regulations regarding the licensure of practical nurses, and standards for accreditation of schools of practical nursing have been determined.

An advisory committee composed of representatives from vocational education, practical nurse education, professional nursing groups, hospital, dietetic and medical organizations, the Minnesota Practical Nurses Association, and the Women's Division of the Farm Bureau Federation was organized. This committee has given helpful suggestions to the board in its new undertaking. Miss Ella Mae Thompson, president of the National Association for Practical Nurse Education, served in an advisory capacity for one week during the period when the standards for accredited schools were being formulated.

The working manual containing standards and guides for schools of practical nursing has been sent to fourteen schools; in addition, several other agencies which are considering establishment of schools have copies.

The law is a permissive one and does not prohibit anyone from nursing the sick for hire, who does not assume or represent to be a Licensed Practical Nurse. The abbreviation, L.P.N., is official for those who receive licenses. In order to qualify, applicants must have at least eighth grade education or its equivalent, be at least 18 years of age, possess good health and character, and have graduated from an accredited school of practical nursing or its equivalent. Among these equivalents are at least two years of general experience in practical nursing under the supervision and direction of physicians and registered nurses. In some instances, applicants may qualify with less than two years' experience because of education in a school of basic professional nursing, or because of training as hospital corpsman, et cetera, in military service.

On February 21, the first examination was held in Mankato, Moorhead, Duluth, and St. Paul. Four hundred and sixty-one practical nurses wrote at that time. Of this number, 187 were graduates of the Vocational Hospital School of Practical Nursing, Minneapolis; forty-two from the Franklin Hospital School of Practical Nursing in Minneapolis, and fourteen from the Union Hospital School in New Ulm. Of this group, 424 or 92 per cent passed and were granted licenses. The next examination will be held in August or September, 1948.

AMERICAN PUBLIC HEALTH ASSOCIATION

The executive board of the American Public Health Association has announced the seventy-sixth annual meeting of the association as taking place in Boston, Massachusetts, November 8 to November 12, inclusive, 1948.

This congress of professional public health workers is the largest of its kind held anywhere in the world. It will be attended by representatives from all parts of the United States, Canada, Cuba and Mexico, and from Latin American countries. Delegates from Europe and Asia are also expected.

Meeting with the American Public Health Association will be many related organizations which select the same time and place as the association for their annual meetings. Among them are:

American School Health Association
Association of Maternal and Child Health and Crippled Children's Directors
Association of Reserve Officers of the U. S. Public Health Service
Association of State and Territorial Health Officers
Conference of Municipal Public Health Engineers
Conference of Professors of Preventive Medicine
Conference of State and Provincial Public Health Laboratory Directors
Conference of State Directors of Health Education
Council of State Directors of Public Health Nursing
National Committee of Health Council Executives
Public Health Cancer Association

An extensive scientific program is in preparation, with the current problems in mind of public health dentists, engineers, epidemiologists, food and nutrition specialists, health officers, industrial hygienists, laboratory workers, maternal and child health experts, public health educators, public health nurses, school health specialists and vital statisticians.

The membership of the American Public Health Association now approaches 12,000 and an attendance of 4,000 is anticipated at the Boston meeting. Dr. Reginald M. Atwater is the association's executive secretary, with offices at 1790 Broadway, New York 19, N. Y.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

TOP GRADE MEDICAL CARE IS DOCTOR'S FIRST DUTY

Doctors of medicine can be of greatest service to the public in three ways—by providing top grade medical care, by promoting public health and by acting as counsellors and leaders in community life.

This was the conclusion reached at the annual County Officers' Meeting held February 28 in Saint Paul. Purpose of the meeting was to discover ways in which medicine can increase its usefulness to the public. A panel of physicians reported on public service activities now being carried on by the Minnesota State Medical Association.

Following this, a forum entitled "The Public Speaks" was held, at which representatives of labor, rural groups and the press suggested ways in which medicine can improve its services.

High quality medical care, administered by qualified and conscientious physicians should be the first consideration of the medical profession when it seeks ways in which it can be most helpful to the public, it was suggested. This does not rule out health education. However, radio programs, health releases and the like are merely adjuncts of top grade medical care.

Advocates Professional Unity

Speaking on the need for interprofessional cooperation, Dr. Charles G. Sheppard, Hutchinson, advocated unity of the medical profession, itself, as the first step. Without good family relations, he warned, the profession cannot function at its best. Having achieved internal unity, the medical profession must strive to promote friendly cooperation and relationships with members of the other professions dealing in health matters—dentists, nurses, pharmacists, hospital administrators, social service workers and others. Public health problems, Dr. Sheppard said, can best be solved through the joint efforts of all of these groups.

Dr. Sheppard called special attention to the work being done by the State Department of Health and praised the department for its "aggressive stand against inroads of socialized medicine whenever that apparition has reared its head in federal state health programs."

The work of the MSMA's Committee on Rural Medical Service was described by the chairman, Dr. Paul C. Leck, Austin. He advocated the establishment of health councils in the communities throughout the state which will bring together all organizations, voluntary and official, having an interest in health and welfare. He reported that preliminary steps were taken recently to establish health councils in several communities. Groundwork has been laid in Austin, Worthington, Fergus Falls and Mankato to bring together various groups to discuss plans. Dr. Leck expressed the hope that these councils will be established in the near future.

Public Policy Outlined

The five-point program of the Association's Committee on Public Policy was outlined by the chairman, Dr. Reuben F. Erickson, as follows:

1. Information and education for the general public in methods which will bring the highest possible quality of medical and hospital care for everyone, everywhere.

2. Co-operation with all lay and professional groups whose aim is the preservation of professional freedom and continued improvement in individual and national health.

3. Encouragement and promotion of agencies providing medical and hospital services on a voluntary, pre-payment basis.

4. Support of legislation promoting wider and more effective distribution of quality medical care.

5. Defeat of legislation which will result in a lowering of medical standards.

Dr. A. E. Cardle, Association president, speaking on public health education, stressed the importance of keeping the public informed on health matters. He pointed out that the public is often reluctant to seek medical aid simply because it has not been educated to the value of it in preventing as well as curing disease.

Fight Fear and Ignorance

Dr. Cardle told the delegates, "If the people are reluctant to claim protection which is rightfully theirs, it is the medical profession's duty to break down the barriers of fear and ignorance and bring health to the people in spite of their reluctance. Certainly curing disease is hardly more noble than preventing it."

A review of the home-town medical care program for veterans, which has been in operation one year here in Minnesota, was reported by Dr. Ralph H. Creighton, chairman of the Veterans Medical Service Committee. He stressed the importance of this program as a public service activity, saying that veterans deserve the best medical treatment possible and expressing the hope that physicians in the state would continue to cooperate in this effort to provide treatment needed.

It was the duty of your Medical Economics editor to lead off the session by endeavoring to point out the need for public service activities. It is your editor's firm belief that the public will follow the able and sympathetic doctor, and in order for medicine to carry out its programs it must secure the confidence and support of the public. All of these public service activities are important, but they must not be allowed to replace the basic purpose of the high calling of medicine—that of ministering to the sick, the relief of suffering and the prevention of disease insofar as is possible.

Public Wants More Co-operation

During the forum which featured the public viewpoint, the delegates learned that the medical profession needs to provide even more health education, to extend prepayment programs for medical and hospital services and to co-operate more fully with other public-spirited organizations.

Speaking for labor, Mr. Orlin Folwick, public relations counsel for the Minnesota State Federation of Labor, called attention to the fact that workers need perhaps even more health care than any group in the population because of the hazards of their jobs, accidents, et cetera, and the need to keep labor healthy to assure maximum production.

The need for increased co-operation with the press was cited by Mr. Kenneth Crouse, Saint Paul *Dispatch-Pioneer Press* staff writer. Mr. Crouse said that the press regards the medical profession as one of its main allies, since life, death and sickness make up a major part of the day's news.

Representing rural leaders in Minnesota, Mr. J. S. Jones, executive secretary of the Minnesota Farm Bureau federation, discussed the wants and needs of rural people in terms of general better living conditions. In seeking to improve living conditions on farms and in rural communities, he said, people naturally want to enjoy health and medical protection on par with that obtainable in cities. He also stressed the importance of budgeting for medical care and encouraged physicians to use every means to promote the spread of prepayment medical and hospital plans. He pledged the support of farm leaders in this effort.

Public Relations Summarized

A diagnosis and interpretation of the present status of medical public relations was presented at the evening dinner by Mr. Theodore R. Sills of Chicago, public relations counsel to several national organizations, including the American Medical Association. Mr. Sills warned the doctors to watch for and heed "danger signals" in public opinion. Politicians, he said, are watching the public closely; and when they feel that the public is anti-doctor and anti-organized medicine, there will be stringent laws enacted.

Mr. Sills suggested the old rule of public relations be applied: "Do good and tell the people about it." He stressed the fact that public relations is "not a whitewash brush." First comes the "do good." First, he said, medicine must have a constructive public service program; then in addition it must avoid acts which will antagonize the public.

Mr. Sills also pointed out that in order to carry out an effective public relations program, every member of the medical profession, individually, will have to assume his part in establishing good relations with his patients.

RED CROSS DEVELOPS BLOOD BANK PROGRAM

A program to build up supplies of whole blood throughout the country is now under way sponsored by the American Red Cross and directed by Dr. Ross McIntire. The program here in Minnesota is not, however, set to start immediately and probably will not be launched until June of next year. In formulating plans, the American Medical and Hospital Associations and other groups concerned were contacted. It will be up to the medical profession to supervise the program, since a large share of the responsibility for the individual cases in which the blood is used will remain with the attending physician.

The Hennepin County Chapter of the Red Cross will not participate in the program because there is already in existence the Minneapolis War Memorial Blood Bank which will carry out the program of collecting, storing and dispensing blood for that locality.

State Committee Studies Program

The Committee on First Aid and Red Cross of the Minnesota State Medical Association has met to discuss this program. Before considering any action, the committee decided that more specific information about procedures for carrying on the program was necessary. Accordingly, a series of questions was drafted by the committee and sent to Dr. McIntire. In order that doctors in the state may be familiar with the Red Cross proposals, the questions submitted and the replies received are printed here:

1. *Will the donors be grouped, a Wassermann test be done, the Rh factor determined, and blood tested for anti-a-titre; where will these laboratory procedures be carried out?*

All donors will be serologically tested by the Kahn test and in many centers one additional test, such as the Wassermann, Hinton, Mazzini, etc. The blood group will be determined not only by the grouping of the red cells but generally by confirmation using a donor's serum against known cells. The Rh factor will also be determined by the use of at least two diagnostic serums in every case. The group O blood donors will be screened by high-titered anti-A, and anti-B agglutinins, so that certain group O blood donors may be set aside as "safe universal donors." All these procedures are to be carried out in the blood center by technicians suitably qualified and trained under the Red Cross program and supervised by a medical director or medical technical director.

2. *Are there any definite ideas as to the fee the physician may charge for the administration of the blood or plasma?*

Although the blood and blood fractions will be distributed by the Red Cross without charge for these products the matter of hospital service charge and physicians medical charge is in no way jeopardized. Since each blood center will be under the direct supervision of a committee of the local medical society, it will be possible for this organization to suggest a limit on the fee or a standard fee for hospitals or physicians.

3. *Will intravenous sets be furnished and if so, will they be rubber or plastic?*

Intravenous recipient sets, probably of the disposable variety, will be supplied with each unit of blood. These are at present plastic materials with a special nylon filter.

4. *What is the status of the danger of virus hepatitis in the use of this blood and plasma and is it true that irradiation eliminates this danger?*

The problem of serum hepatitis is still being explored by various research laboratories and to date there is no proof that irradiation eliminates this danger. All precautions will be taken as recommended by our advisory committee, made up of experts from all over the country.

5. *Will serum be made available? Will the plan urge cross-matching of the blood in the event that some error might occur in labeling the proper group on the bottle?*

Whole blood, packed red cells, plasma and fractions of plasma will be made available. Serum is not included. The program urges the re-checking of blood specimen tubes attached to each bottle, by the laboratory of the hospital using the blood, and cross-matching is a necessary preliminary.

6. *At what age will blood be discarded or sent in for processing? Will the ACD solution be used to prevent coagulation?*

The blood will be kept for seventy-two hours before distribution, and then since it is in ACD solutions may be used for the following eighteen days. Unused blood will then be re-collected for removal of the plasma for fractionation purposes.

7. *How soon after drawing blood will it be chilled? What will be the recommended degree of chilling?*

In general the bleeding bottles will be precooled before use in a refrigerator at 4 to 10° C. and the blood will be replaced in the refrigerator as soon as it is drawn.

8. *How will distribution centers be selected, especially in remote localities?*

Distribution centers will be selected according to needs and following application from local Red Cross chapters which have met the conditions required by the national organization. One of these conditions is the approval of

the local medical society and all medical groups involved in any community and the formation of a committee by such groups to supervise the activities of the blood center. Remote localities will be served by mobile units both for collection and distribution of blood, although in the latter case even planes may be needed.

9. *If blood from colored individuals is to be drawn, especially in places where there are few colored people, is it to be made available for those colored people or what will be recommended in the use of blood from colored people?*

The position of the American National Red Cross with regard to the segregation of blood from colored donors is that this remains a local prerogative. The Central Committee (formerly the governing body) of the American National Red Cross issued the following statement of policy regarding the segregation of blood in the National Blood Program:

"Inasmuch as, on the basis of recorded scientific and medical opinion, there is no difference in the blood of humans based upon race or color, the plan does not require the segregation of blood; however, whenever necessary to insure the success of the plan, which is to make available blood and blood derivatives to all the people of the United States regardless of race or color, chapters will collect and hold blood in such a manner as to give the physician and the patient the right of selection at the time of administration."

NATIONAL HEALTH ASSEMBLY CALLED

A ten-year federal health plan for this country is the subject to be discussed by a National Health Assembly being called by the Federal Security Administration for May 1-4, 1948.

It started out as another packed conference similar to the one held in 1938. When news of the conference first broke, it was revealed that out of an executive committee of twenty-four picked by Administrator Oscar R. Ewing, only one was a doctor, George F. Lull, Secretary and General Manager, American Medical Association.

An editorial in the AMA *Journal*, commenting on the obviousness of the health insurance propaganda motives behind the meeting and noting the lack of adequate physician representation, was answered by Mr. Ewing's belated addition of fourteen persons to the executive committee from several groups including the hospital, medical, nursing, dental and public health associations. Administrator Ewing, in announcing the conference, said that he was acting at the request of the President who wants him to develop "feasible national health goals for the next ten years."

Fake Doctor Must Serve One Year in Minneapolis Workhouse

Re State of Minnesota vs. Frank Herman Gold, also known as Frank H. Gould.

On March 8, 1948, Frank Herman Gold, also known as Frank H. Gould, thirty years of age, residing at 300 Fifth Avenue N. E., Minneapolis, was sentenced by the Hon. Levi M. Hall, Judge of the District Court of Hennepin County, to the maximum term of one year in the Minneapolis Workhouse. Gold was sentenced following his plea of guilty to an information charging him with the crime of representing himself to the public as a doctor of medicine without being registered under the Minnesota Basic Science Law. Gold was immediately taken to the Workhouse to commence serving his sentence.

The defendant was arrested on March 3, 1948, by Minneapolis police officers who discovered Gold representing himself to the public as a doctor after having purchased various surgical instruments and medicinal supplies in Saint Paul and Minneapolis. Gold, who was born in New York City and came to Minneapolis in 1941, was previously convicted of the same offense on May 21, 1946, in the District Court of Hennepin County. At that time Gold was placed on probation for one year by Judge Lars O. Rue. Shortly after Gold's probation expired in 1947, he purchased a rubber stamp on which he designated himself as a doctor of medicine. He also purchased the surgical instruments and medicines found in his possession by the Police Department at the time of his arrest. Gold has also married following his previous conviction and represented himself to his wife as a doctor. Gold, at the time of his arrest, was an employe of a Minneapolis bakery. During the seven years that Gold has resided in Minneapolis, he has been employed as an orderly at two Minneapolis hospitals and he has also worked as a clerk in three Twin City drug stores.

Former Minneapolis Abortionist Sentenced to Two Years in Federal Prison

Re State of Minnesota vs. James Lloyd Beckman

On March 16, 1948, James Lloyd Beckman, thirty-six years of age, 3425 Portland Avenue, Minneapolis, was ordered by the Hon. M. M. Joyce, Judge of the United States District Court, to serve two years in a Federal institution to be designated by the Attorney General of the United States. Beckman was brought into Federal Court following his release from the Stillwater Prison on February 24, 1948, where he had served a three-year sentence imposed by Judge Frank E. Reed of the District Court of Hennepin County on November 7, 1945,

Former Minneapolis Abortionist Sentenced to Two Years in Federal Prison

(Continued from Page 403)

on which date Beckman entered a plea of guilty to an information charging him with the crime of abortion.

At the time Beckman pleaded guilty to abortion in the District Court of Hennepin County, he was on probation in the United States District Court because of his failure to report for induction into the United States Army. That probation was imposed by Judge Joyce, on October 13, 1942, on which date Beckman was sentenced to a term of three years in a penitentiary type institution for violating the Selective Service Act. On the same date Judge Joyce suspended for five years the imposition of sentence on Beckman for a second indictment charging him with failure to report for induction into the United States Army. Beckman served part of the three-year sentence at Leavenworth, Kansas, and Sandstone, Minnesota. He was released on parole December 14, 1944, so that he could join the United States Army. Beckman remained in the Army but a short period of time and received a medical discharge. Since then he has been receiving a pension of $69.00 a month from the Government for his army service following a claim of a heart ailment. Beckman violated his probation in Federal Court by being convicted of the abortion charge in November, 1945. No action was taken by the Court on revoking Beckman's probation until he served his full sentence on the abortion charge.

On March 16, 1948, when Judge Joyce revoked Beckman's probation, the Court told Beckman that engaging in the abortion racket was "one of the rottenest lines that a man could engage in." In reviewing Beckman's long criminal record dating back to 1931, when he was arrested for stealing from a Minneapolis department store, Judge Joyce stated that "not one single item of proof that there is any good in this man" had been offered to the Court. Beckman never was licensed to practice any form of healing in the State of Minnesota.

CONGENITAL CYSTS AND FISTULAS OF THE NECK
With Case Reports

WILLIAM H. RUCKER, M.D., F.A.C.S.
Minneapolis, Minnesota

Congenital cysts and fistulas of the neck are interesting surgical problems. A knowledge of the embryology and anatomy of the cervical region is necessary for their recognition as well as the delicate dissections required for their adequate removal. This treatise concerns itself with a discussion of a number of these anomalies and the reporting of one case of each type.

Thyroglossal Duct Cysts and Fistulas

The thyroglossal cyst has its origin in a duct which arises at the foramen cecum in the embryo, passes down through the base of the tongue, over, through, or under the hyoid bone, and into the neck to form the isthmus of the thyroid gland. When this duct does not become obliterated, a cyst may result from the secretion of its epithelial lining. Commonly this occurs below the hyoid bone, but at times above it, and in a few cases just below the foramen cecum.

One is usually consulted by a young person who wishes a lump removed from the neck for cosmetic reasons. On examination, a round or ovoid cystic feeling tumor, ordinarily about the size of a walnut, is found just inferior to the hyoid bone in the mid-line, or occasionally to one side. There is no tenderness unless inflammation is present, which is uncommon unless aspiration or incision has superimposed infection. Less often, a cyst is seen above the hyoid bone, which is frequently larger and appears as a soft tumor in the mid-line beneath the chin, at times protruding into the floor of the mouth, but producing few symptoms. On rare occasions, a cyst may bulge the tongue in the region of the foramen cecum and interfere with deglutition and respiration.

The differential diagnosis of these lesions is ordinarily not difficult, but epidermoids, branchial cysts, thyroid cysts, and aberrant thyroids must be considered. Epidermoids are attached intimately to the skin and do not move with deglutition. The relationship of branchial cysts to the sternomastoid muscle should distinguish them, as thyroglossal duct cysts rarely extend to this muscle. Thyroid cysts are connected commonly with the thyroid gland, but aberrant thyroid tissue may be located anywhere along the course of the thyroglossal tract and may be impossible to differentiate. Infection may confuse the diagnosis.

Thyroglossal duct cysts are freely moveable beneath the prethyroid muscles except at their base where the duct passes to the hyoid bone. They are smooth walled and contain a mucoid material, unless infected, when granulation tissue and pus may be present. They may be lined with flat or cuboidal epithelium, and papillary projections may be found. Many times no epithelium is seen.

Thyroglossal duct fistulas practically all occur as a result of infected thyroglossal cysts and the procedures incident to their treatment. In rare cases they are present from birth and appear as small openings in the mid-line of the neck below the cricoid cartilage, discharging intermittently or continuously a mucoid or purulent material. They are lined with squamous epithelium.

Total excision is the only satisfactory treatment for these cysts and fistulas. They will recur if portions of the cyst wall, duct, or diverticuli from the duct have not been removed. The procedure reported by Sistrunk[14 15] in 1920 has been uniformly successful. This operation consists in dissecting free the cyst to its base, excising a portion of the hyoid bone, and the tract *en bloc* in a 45 degree angle to the base of the tongue.

Case Report

A fourteen-year-old boy was admitted to the hospital January 8, 1939, for the removal of a tumor which had been present on his neck for three months. He stated he had first noticed the lump in the fall of 1938 and that it had gradually increased in size. It had caused him no discomfort, but he wished it removed because "it looked bad."

Physical examination revealed a rather tense cystic-feeling tumor, about the size of a walnut, on the left side of his neck over the cornu of the hyoid bone. The skin was freely moveable over it, and it moved up and down as the patient swallowed. There was no tenderness nor other evidence of infection.

A diagnosis of thyroglossal cyst was made and operation performed on January 9, 1939. The Sistrunk operation was used. An uneventful recovery took place, and there has been no recurrence.

The report of the pathologist revealed a 2-centimeter cyst filled with mucus. Microscopically a fibrous wall was found with no apparent epithelial lining, but lymphocytes and pus cells infiltrated the wall and at one point an irregular gland lined with epithelium was found.

Branchial Cysts

The origin of branchial cysts and fistulas is still controversial. In 1832, Ascherson[3] suggested that they probably arose from the branchial apparatus, and in the late 1800's through the writings of Heusinger and Senn,[9] they became known as branchial cysts and fistulas. However, Wenglowski[19] in 1912, after the study of seventy-five embryos and five years' work, asserted that these lesions did not arise directly from the branchial clefts but from the primordium of the thymus. He stated that the branchial clefts were only involved in the development of the head and upper neck and that they could have nothing to do with any defect below the hyoid bone. He concluded that these cysts and fistulas arise from the thymic ducts which have their origin in the third branchial pouch. In 1932, Meyer[12] reviewed Wenglowski's work and agreed with him. Nevertheless, many prominent authors are satisfied with the concept of their branchiogenic origin. They argue that the course of the branchial fistula is incompatible with the route of the thymo-pharyngeal duct—the fistula passing anterior to the hypoglossal nerve and between the external and internal carotid arteries, and the duct passing posterior to the internal carotid and inferior to the nerve[11]—that none of these anomalies have ever been found in the mediastinum in the region of the thymus;[7] that cartilagenous auricles occur in the lower neck and are undoubtedly remnants from the branchial apparatus;[4,15] and that at two months in the embryo the branchial apparatus has disappeared, so that it cannot be definitely stated that the hyoid bone marks its lower limits.[15]

Branchial cysts are deep-seated globular tumors which occur along the anterior margin of the sternomastoid muscle, usually under the angle of the jaw. They may bulge into the floor of the mouth, extend under the sternomastoid and even appear posterior, or continue along its anterior border and result in considerable enlargement of the neck. They are usually not evident until adult age, in spite of their congenital origin, and often become more prominent after an upper respiratory infection. They may occur on either side of the neck, usually grow slowly, unless infected or traumatized, and may be present for many years before medical advice is sought. These lesions may become spontaneously infected, but more often infection follows inadvertant incision. To palpation, they are smooth and cystic, or hard, depending upon their content, which may be either fluid or cheesy. They do not transilluminate, and unless inflammation has been present, they are moveable beneath the skin.

Branchial cysts must be differentiated from tuberculous lymph glands, cold abscesses, suppurating lymph glands, dermoid cysts, hygromas, aberrant thyroids, lipomas, hemangiomas, neurofibromas, metastatic nodes, aneurysms and carotid body tumors. Diagnosis can usually be made by a careful history, a thorough physical examination, aspiration, and x-ray study. The history will often reveal points of diagnostic value. On physical examination, the relationship of the branchial cyst to the sternomastoid muscle, its nonadherency to the skin, its opaqueness to transillumination, and its tense cystic consistency with no pulsation will be distinguishing factors. Aspiration is a helpful differential procedure. Bailey[4] states that the presence of cholesterol crystals in the aspirated fluid will always demonstrate a branchial cyst. Wangensteen[18] reports the shimmer or yellowish sheen of the fluid in a basin is characteristic. Wangensteen also found that he could differentiate these cysts from tuberculous glands by x-raying them after the injection of an opaque material.

Bailey[4] classified branchial cysts into four types, using as a basis their relationship to other structures of the neck: Type I lying just below the cervical fascia at the anterior border of the sternomastoid, its center just opposite the great cornu of the hyoid bone; Type II, the most common, lying on the internal jugular vein; Type III extending between the internal and external carotid arteries towards the pharynx and at times even to the base of the skull; Type IV, the columnar lined cysts, lying in contact with the pharynx but giving rise to no symptoms.

Neel and Pemberton[13] state branchial cysts vary in size from .1 centimeter to more than 10 centimeters and that they have walls varying in thickness from 1 millimeter to 1 centimeter. They are ovoid or spherical shaped tumors, usually lined with squamous, but occasionally with columnar epithelium. Their content may be clear, milky or cheeselike, but it always contains cholesterol.

The treatment is surgical removal. Through a transverse incision, which follows a natural crease in the neck, the skin and platysma muscle are sectioned and pulled aside. The fascia is cut and the sternomastoid retracted, or incised if necessary. The cyst should not be ruptured. Bailey[4] advises partial aspiration and then grasping the wall with a sponge holder with gauze between the rings. Great care must be exercised as one proceeds, as these cysts are often adherent to the jugular and carotids, near the hypoglossal and glossopharyngeal nerves, and sometimes in contact with the pharynx in the tonsil area. All of the cyst wall must be removed or destroyed to prevent recurrence.

Case Report

On June 21, 1943, a negro, fifty-four years of age, was seen because of a mass on the left side of his neck—a growth that had been present for six weeks had gradually increased in size, but had caused no symptoms. He had had two x-ray treatments.

An ovoid tumor about the size of an egg was present at the anterior edge and under the left sternomastoid muscle, about an inch below the angle of the jaw. Palpation elicited a hard tumor adherent to surrounding tissue. There was a moderate redness and induration of the overlying skin from the x-ray therapy. The patient's temperature was normal and other findings were unimportant.

Operation was performed June 22. A transverse incision was made over the mass. It was found adherent to the sternomastoid muscle, making it necessary to split and dissect the muscle from the tumor's surface. It was also fused to the deeper structures and could not be removed intact. As it was opened, a milky purulent material exuded. The cyst wall was stripped away and the cavity cauterized with phenol. A drain was inserted and the wound was closed.

Sections of the cyst wall showed fibrous tissue with chronic inflammation and granulations infected with pus

Swabs of the contents taken at operation showed hemolytic streptococci.

The patient made an uneventful recovery and has had no recurrence to date.

Branchial Fistulas

Branchial fistulas may be present at birth or may occur as the result of incising a branchial cyst. Three types are found: the complete type, where the fistula has an internal opening in the pharynx and an external opening along the anterior border of the sternomastoid; the internal type, which opens in the pharynx; and the external type, which has only an external orifice. They are usually unilateral but may occur on both sides of the neck. When these fistulas arise from the first branchial cleft, their openings are on or near the ear, ordinarily incomplete, and causing no symptoms except slight intermittent drainage.

Branchial fistulas from the cervical sinus or thymic duct are practically always located in the lower third of the neck with their external opening along the anterior border of the sternomastoid muscle and their inner sinus in the posterior pillar of the tonsil. They are prone to excrete intermittently a mucoid fluid except when infection causes a purulent discharge. They are lined with squamous or cuboidal epithelium.

Diagnosis presents no problem. Treatment consists in removal of the complete tract when inflammation has subsided. X-ray after the injection of opaque media is valuable in demonstrating the course of the lesion. Yoerg[20] has discovered a helpful procedure which is adaptable to any fistulous tract and valuable here. If, following the injection of lipiodol, methylene blue is injected, a bluish-black substance is fixed in the fistulous wall and dissection is greatly facilitated. However, these tracts hold only a small amount of solution and one must be careful not to rupture them and force the dye into the surrounding tissues.

As vertical incisions in the neck often leave ugly scars, a transverse elliptical incision should be made about the fistulous opening, and the tract followed up over the prethyroid muscles and then deeply over the hypoglossal nerve and between the internal and external carotid arteries towards the pharynx. Dissection should be carried as far as safely possible and the stump ligated, excised, and cauterized. Von Hacker's or Koenig's methods of inverting the stump into the pharynx are probably not necessary, if the stump is short. Usually one incision in the skin, if widely retracted, will suffice, but if necessary, another steplike transverse incision may be made above and the dissection carried on from there.

Report of a Case with Bilateral Cervical Fistulas and an Auricular Sinus

History.—On July 9, 1947, a sixteen-year-old girl entered the hospital because of fistulas which had been present on either side of her neck since birth. The one on the right had intermittently swelled and discharged a creamy material. From the one on the left she noted in rare instances a drop or two of clear fluid, but no swelling or irritation. In front of her left ear a small opening had been noticed from birth but had caused her no concern.

Physical examination.—On the right side of the neck, 5 centimeters from the sternal notch, at the medial margin of the sternomastoid muscle, there was a small sinus from which could be expressed a whitish creamy material. There was no swelling, redness or evidence of inflammation. Along the medial border of the left sternomastoid muscle, 2.5 centimeters from the sternal notch, there was a small fistulous opening emitting no discharge and not infected. Just anterior to the helix of the left ear, there was a small nondraining sinus 1 centimeter in depth. Her tonsils had been removed. Internal fistulous openings could not be found in the posterior pillars. X-ray examination after injection of pantopaque revealed fistulas.

Operation.—On July 10, lipiodal and methylene blue were injected into the right fistulous tract. An elliptical incision was made about the opening, and the dye-stained tract was dissected up between the branches of the carotid artery to the tonsil area where it was ligated and excised. A small rubber drain was inserted, the wound closed and layers with clips adapting the skin margins. Healing was prompt and a fine linear scar resulted.

Pathological Report.—The specimen consisted of a branchial fistula removed intact. It was covered by skin and measured 6 by 1 centimeters. The fistulous tract was elongated and showed no definite cystic dilatation. It had been injected with methylene blue.

Operation.—On August 12, 1947, the fistulous tract on the left was removed in a similar manner. However, as it was located lower in the neck and hence was longer, another steplike incision above was necessitated for its complete removal. Recovery was rapid and the scar was good.

Pathological Report.—The specimen consisted of a portion of the skin from the neck, attached to which was an elongated portion of tissue stained with methylene blue, resembling a sinus tract. Microscopic sections of the sinus showed it to be lined by noncornified epithelium, surrounded by a few lymphocytes, muscle and connective tissue. There was no evidence of malignancy. Diagnosis: Branchial fistula of the neck.

Cystic Hygroma

Cystic hygromas are comparatively rare. Although Gross and Goeringer[8] reported twenty-seven cases in 1939, they could find only about 225 cases, including theirs, in the literature at that time.

These cystic tumors are of lymphoid origin and arise from the embryological jugular and subclavian lymph sacs, anlagen of the cervical lymphatic system. Normally these sacs send out branches which anastomose with other branches from similar sacs in the pelvic, abdominal, and thoracic regions, to form the lymphatic system. Sabin[14] believes the sacs are off-shoots of the venous system while Huntington[10] asserts they develop from mesenchymal tissues. Whatever their origin, there is general agreement that the hygroma arises from disconnected portions of these sacs which continue to grow by sending out endothelial cords between tissues of the neck, these cords later acquiring lumen which fill with lymphlike fluid. As the jugular sac extends from the jugular foramen to the subclavian region under the clavicle, the locations of these lesions can be explained.

Cystic hygromas are doughy spongy-feeling tumors that are often present at birth. In Gross and Goeringer's[8] cases, 90 per cent were noticed before the child

was two years of age. A few have been reported in adults. They usually occur in the supraclavicular space, where they vary in size from a barely palpable mass to a cyst involving the entire lateral side of the neck. On rare occasions they extend into the mediastinum. Eight of these cases had been reported when Arnheim[2] reported two in 1932. A few occur at the angle of the jaw. Crying or coughing cause them to become more tense and evident. They are usually symptomless but may, through pressure, interfere with deglutition and respiration. They can become infected from the pharynx or through surgical interference. The overlying skin is thin and often has a bluish tint. Unless hemorrhage has occurred within them, they may be transilluminated.

Hygromata are endothelial-lined, usually multilocular, but occasionally monolocular cysts containing a straw-colored or blood-tinged lymphlike fluid. Projections protrude between muscle and fascial planes and surround nerves and blood vessels, making removal difficult and not without danger.

These cysts must be differentiated from hemangiomas, lipomas, dermoids, branchial cysts and abscesses. Usually the diagnosis is not difficult when they lie in the supraclavicular region. The peculiar doughy consistency of the mass is typical. Hemangiomas are usually compressible and cannot be transilluminated. Lipomas and dermoids are entirely different in consistency and also can be ruled out by aspiration. Branchial cysts are more tense and have a definite outline. Their location is typical, and they do not transilluminate. Confusion may arise when the tumor is located at the angle of the jaw, but palpation, transillumination and aspiration should give conclusive evidence.

Treatment consists in radical excision, which may be difficult because of the ramifications of this thin-walled growth. When it extends into the mediastinum, removal is usually impossible and x-ray therapy must be relied upon. Recovery has followed infection. Cures have taken place after aspirations, injections of sclerosing agents, x-ray and radium therapy, but these types of treatment are usually unsuccessful and dangerous. Expectant treatment may allow infection and a critical outcome. These lesions should be approached through a transverse incision following the skin creases, and all of the tumor must be removed. If remnants remain, the cyst will reoccur, frequently in a short time. Dowd[6] reports a recurrence in twenty-five days.

Case Report

On May 24, 1946, a male child, ten months of age, was admitted to the hospital because of a tumor of the neck which the parents had first noticed when the child was two months old.

When the boy was six weeks old, the parents noted a tendency of the baby to hold his head towards the left. Some two weeks later they noticed a lump on the right side of the neck and consulted Dr. Platou. The cyst was aspirated and about 5 centimeters of blood-tinged fluid removed. Operation was advised. On December 28, the baby was brought to the hospital but developed an upper respiratory infection and operation was deferred. At this time, an x-ray was taken of the neck. There was no apparent enlargement of the mass from the time it was first noted. However, the parents thought it was more evident at times.

The baby had been born by cesarean section because of toxemia in the mother, had been breast fed, development had been normal, and the child had been healthy except for the upper respiratory infection in December. The father has a congenital clubfoot.

On physical examination, this male child proved normal except for a growth in the left supraclavicular space. The overlying skin was thin and had a bluish tint. Transillumination was not possible. The cyst had a peculiar soft doughy feel and was difficult to outline. When the baby cried, the mass bulged and became more noticeable.

The x-ray report read as follows: "a soft tissue swelling of the right side of the neck extending from approximately the level of the second to the fifth cervical vertebra."

A diagnosis of hygroma or hemangioma was made and operation was performed on May 25, 1946. Through a 5-centimeter incision, the cyst was dissected free of its many attachments and removed. It projected between muscle and fascial planes, was attached to the jugular vein and in intimate relationship with the brachial plexus. The wound was closed with one drain. The baby made an uneventful recovery, and there has been no recurrence.

The cyst was multilocular, very thin-walled and contained a rusty or blood-tinged fluid. The pathological report read as follows: "A section reveals lymph, adipose tissue, nerve fibers, and muscle surrounding a large cystic space lined with endothelium. Diagnosis: Lymphangioma of the neck."

Hemangiomas

Deep hemangiomas of the neck are not common. They are soft cystic tumors which often can be evacuated on pressure. Their usual location is near the clavicle in the supraclavicular fossa.

Case Report

On August 13, 1945, a baby girl, eight months of age, was seen in consultation with Dr. Trueman. This baby had a soft fluctuant tumor of the neck just above the sternal notch, which had been noticed for two months. On August 5, the cyst had been aspirated of a bloody fluid, lipiodol injected, x-rays taken, and a cyst diagnosed. Operation was thought indicated.

A collar incision was made and a 2-centimeter cyst removed from the region of the sternal notch along with four smaller dilated vessel segments with little or no connection with the vascular system. These tumors were below the fascia in the mid-line, some extending up to the region of the right lobe of the thyroid.

The pathological report was as follows: "Cystlike tumors of the neck. Section shows blood vessels of various sizes, several of which contain free blood, others being empty. Scarring preformed vascular tissue and minimal round cell infiltrate are also noted. Multiple hemangioma."

Summary

The embryology, clinical aspects, and treatment of a number of congenital defects of the neck have been discussed and a case of each type reported. Several conclusions would appear to be evident:

1. A knowledge of embryology is essential in the recognition and treatment of these lesions.
2. Transillumination, aspiration, and x-ray are helpful procedures in their differential diagnosis.
3. Total excisions prevent recurrence.
4. Staining of the fistulous tracts with lipiodal and methylene blue is of value in their safe and adequate removal.

5. Skin incisions should follow natural creases in the neck to give good cosmetic results.

Discussion

Dr. Martin Nordland: It has been a pleasure to listen to this very interesting discussion of fistulas of the neck by Dr. William Rucker. The occurrence of congenital lesions of the neck is not rare, but in the experience of most surgeons these patients come for treatment rather seldom.

There are a few things relative to the care of the patient with the congenital lesion of the neck that I wish to emphasize. In the first place, because the attending physician does not realize the importance of the radical excision of these lesions the first time the patient is treated, inadequate cure often results. Many times the patient at the original treatment has had a simple incision made in the cyst, resulting in an unhealed fistula. Unusual swelling in the neck in the locations which Dr. Rucker has described should always be considered congenital in origin, and thorough treatment administered the first time. Secondly, it is taken for granted many times that the operative procedure for a cure is a simple one. On the contrary, it can become a very difficult dissection, and preoperative precautions should be taken for a meticulous and difficult job in order to obtain a thorough cure. Attention to the position of the patient on the table is very important. Good exposure is necessary. The position of a patient for a thyroidectomy makes a good position for the surgical treatment of such lesions.

The classical Sistrunk operation for the cure of thyroglossal duct cyst is still the best treatment, as Dr. Rucker has described. One point in the procedure which is worth while emphasizing is that it is always necessary to remove the segment of the hyoid bone as described in the technique. Many of these tracts continue above the hyoid bone to the cecum of the tongue.

Two things are important to mention in the treatment of a branchial cyst. First, the use of lipiodal and methylene blue in small quantity makes it easier to follow the tract in the dissection. The second, and a very important point, is one that Dr. Rucker made with reference to the incision. I think it is a serious mistake to make an oblique incision along the anterior border of the sternomastoid muscle. This always results in an ugly scar. The cosmetic result is very important, particularly in a young woman. Any and all of these lesions can be removed very well through one or more transverse incisions along the natural lines of the neck. I have two very interesting slides which show the value of the introduction of opaque lipiodal with methylene blue. The first slide shows the extent of the lesion. The second slide shows an x-ray picture of the specimen and also that the entire tract was removed.

Dr. Otto W. Yoerg: I was privileged to read Dr. Rucker's paper, and after hearing his presentation tonight, I can now fully appreciate the effort and study that was necessary to make his thesis on congenital cysts of the neck so complete and interesting.

Many of you may not know that Dr. Rucker is an artist. All of the drawings shown on the slides were made by Dr. Rucker.

The contrast media which Dr. Rucker mentioned were first described in a paper on cysts of the urachus which I presented to the Minnesota Academy of Medicine on April 8, 1944. We had injected the sinus of the urachus cyst with lipiodol for x-raying just before surgery. Methylene blue was injected which, to my surprise, when coming in contact with the iodide produced an india black precipitate, which remained fixed in the tract, allowing the dissection of the tract and cyst to be made with ease. I have used this procedure in cysts of the neck, pilonidal sinuses, bowel fistulas, and various other sinuses with gratifying results.

I want to congratulate Dr. Rucker for a splendid paper and feel that the surgical society is privileged to have him as a member.

Dr. A. F. Bratrud: A number of years ago, Dr. Robitshek reported two cases of branchial cysts of the neck which were treated by injecting Carnoys' solution. Several articles appeared in different journals at that time. Dr. Rucker stated that it is rather dangerous to use sclerosing solution in the treatment of any congenital cysts of the neck. I have injected two cases of branchial cysts with very excellent results and without complications.

I would like to know the contraindication for using sclerosing solution in the treatment of these cases. It is not practical to inject thyroglossal cysts with sclerosing solution, as they do not lend themselves to this type of treatment at all, as there may be multiple tracts leading from a thyroglossal cyst.

Previously, when these articles were printed, they gave one contraindication to the use of sclerosing or Carnoys' solution in the treatment of these cysts. They should not be used where the fistula tract extends into the pharynx.

I remember seeing Dr. Gustav Schwyzer operate on a patient with a branchial cyst. He went into the pharynx on two separate occasions and had rather great difficulty in closing. With proper care in the use of Carnoys' solution, I cannot see any objection to this type of treatment when you consider the difficult surgery of branchial cysts. I would also like to ask Dr. Rucker what the incidence of malignancy is in branchial cysts.

Dr. William H. Rucker: I wish to thank Doctors Nordland, Bratrud, and Yoerg for their kind remarks. Dr. Bratrud, I have had no experience with injecting sclerosing solution into branchial cysts, but I do not believe it is a good procedure. Reports in the literature are not favorable. As to the other question, malignancy, I believe, occurs in less than 1 per cent of these lesions.

TREATMENT OF ULCERATIVE COLITIS WITH PROPYLTHIOURACIL

A. B. ROEHLKE, M.D., and GORDON TESCH, M.D.
Elk River, Minnesota

Lawrence Martin[1] of Cambridge, England, in 1946 reported four cases of ulcerative colitis treated with thiouracil in which he obtained clinical benefit in all cases, and improvement in the ulceration of two of these. Later examination revealed improvement in the remaining two. Martin stated that hypothyroidism was not produced, as evidenced by normal basal metabolic rate. He also emphasized the fact that further trials are necessary before any definite claims can be established, though he considered it "justifiable to test any empirical remedy however devoid of logical basis it may appear." He stated that thiouracil is chemically similar to synthetic 5-methyluracil which was used effectively by Spiess et al[2] for the diarrhea of tropical sprue.

An opportunity was presented to try propylthiouracil on one of our cases.

Case Report

A girl, aged twenty-one, was admitted to the St. Barnabas Hospital on July 18, 1947, giving a history of having suffered from ulcerative colitis with numerous exacerbations for the past two years. She had been in the St. Barnabas Hospital on two other occasions, at which time vaccine therapy, dietary regime and chemotherapy had been given with only partial and temporary benefit.

She was markedly malnourished. She weighed 76 pounds. The hemoglobin was 70 per cent. Her serum albumin was 3.6 mg. per cent; serum globulin, 1.0 mg. per cent. The stool was packed with pus cells, and occult blood, four plus, was found. X-ray examination revealed extensive ulceration involving the entire colon. Sigmoidoscopic examination revealed ulceration starting at the dentate line and extending upward as far as could be seen. The mucosa bled freely.

Medical management was instituted without significant benefit. The temperature was septic in character, spiking from day to day from 100° F. to 104.2° F. Penicillin, streptomycin and dietary treatment were instituted without much benefit.

Dr. Carl O. Rice was called in consultation with the idea of preparing her for vagotomy, somewhat in accordance with the plan discussed by Dr. Dennis this evening. Parenteral feeding of glucose, amigen and alcohol were added to her oral feedings, so that her total caloric intake was maintained between 3,000 and 5,000 calories without forcing the oral feedings. The septic type of temperature reaction subsided during this period of treatment. No weight gain was observed, and it was therefore decided to resume dietary regime by mouth. The septic type of temperature reaction returned when the parenteral feedings were stopped, perhaps coincidentally, and within four or five days the patient asked to be discharged. She then weighed 75 pounds. She was discharged. Fifty-two days of hospital management had accomplished no significant benefit. Six to ten small bloody, foul-smelling stool evacuations persisted.

This situation prevailed at home for several days until 50 mg. of propylthiouracil was administered four times daily the first week, then three times a day. Almost immediately her diarrhea improved, stools became formed, and within a few days they were limited to one or two stools per day. In the first seven days she had gained 5 pounds in weight, and at the end of fourteen days she had gained 10 pounds.

Colon roentgenograms taken in November, 1947, still revealed the same findings as formerly reported, and proctoscopic examination on December 2, 1947, indicated definite improvement: a grey granular appearance, but no blood. There was some purulent exudate. The basal metabolic rate on November 11, 1947, was found to be plus 9. The menses was absent for seven months, until last week when she again had a normal menstruation.

She continued to remain clinically relieved. She now feels well, has gained interest in life, and though slightly lethargic, weighs 101 pounds. She has been receiving propylthiouracil for ninety days with no exacerbation of symptoms.

An explanation for the cause of improvement in this case cannot be given. We merely wish to say that a disease as destructive to life and health and unamenable to treatment as ulcerative colitis deserves the benefit of any empirical remedy no matter how void of rationality it may appear.

We have been happy to have the opportunity to present this brief case report to the Minneapolis Surgical society in hope that some of you may find occasion to try it before venturing into irreversible surgical substitution for the alleviation of the distressing symptoms of ulcerative colitis. We have been repeatedly advised by one of your members that a good surgeon is one who knows when not to operate.

Addendum

April 6, 1948—The patient continues to remain free of symptoms. This is the longest remission the patient has experienced since the onset of her first symptoms in July, 1945.

Discussion

Dr. Clarence Dennis: Sometimes the patients are smarter than the doctor, and this is one of those times. I was among the physicians who were outsmarted by the patient. I didn't see her, but Dr. Rice was concerned about her care. Dr. Rice asked my opinion about it and gave me her story. I said I thought she would respond well to vagotomy. We have been familiar with the work of Martin and had given thiouracil to many of our patients. We have a couple in which we are defeated as far as operation is concerned. They will have a trial on propylthiouracil.

Dr. Leo Culligan: May I know the effect of thiouracil on the normal thyroid?

Dr. Martin Nordland: I have never tried it on the normal thyroid.

Dr. Clarence Dennis: I think myxedema can be produced with thiouracil.

Dr. Martin Nordland: Of that I am sure. I recently operated upon a patient who had had considerable thiouracil previous to a thyroidectomy. She was one of the patients who revealed the danger of this drug. When I first saw her, she had a temperature of 103°, marked cervical adenitis, agranulocytosis, and leukopenia. After recovery from these severe symptoms, a thyroidectomy was done. She was under the care of an internist preoperatively and postoperatively. Since operation she has developed a marked myxedema. Preoperatively she had a marked hyperthyroidism. I cannot believe that the operation alone could have accounted for this severe myxedema.

Minnesota Academy of Medicine

Meeting of December 10, 1947

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 10, 1947. Dinner was served at 7:00 p.m., and the meeting was called to order at 8:00 p.m. by the president, D. E. M. Hammes.

There were fifty members and three guests present.

Minutes of the November meeting were read and approved.

Drs. Goltz, Kenefick and Drake were appointed on a committee to draw up a memorial to Dr. A. R. Hall.

The following were elected as officers for 1948:

President.....Dr. T. A. Peppard, Minneapolis
Vice President.....Dr. J. A. Lepak, Saint Paul
Secretary-Treasurer..Dr. A. E. Cardle (re-elected)

The scientific program followed. Dr. R. T. La Vake, Minneapolis, presented a paper, after which Dr. Jerome Hilger, Saint Paul, read his inaugural thesis.

SEROLOGIC OBSERVATIONS IN THE TOXEMIAS OF PREGNANCY

R. T. LA VAKE, M.D.
Minneapolis, Minnesota

(Dr. La Vake's paper, followed by a discussion of it, appears on page 372 of this issue.)

AUTONOMIC DYSFUNCTION IN THE INNER EAR

JEROME HILGER, M.D., M.S. (In Otolar.)
Saint Paul, Minnesota

The autonomic nervous system is the mediator in the body's adjustment to its environment. The character of one's autonomic system is a matter of inheritance. There is variation in the quality and performance of the system in different individuals. This fact has been a matter of medical record since very early times. It was given particular impetus by the writings of Eppinger and Hess who in 1909 introduced the clinical pictures of the sympatheticotonic individual and the vagotonic individual into medical literature. It is interesting to follow the emergence of the autonomic system from the anatomic awareness of the nineteenth century to its present position in the forefront of functional clinical medicine. Disease whose pathological basis was then recognized and described only in the textbooks of morbid anatomy is now recognized and intercepted in the stage of early altered physiology—the stage in which autonomic dysfunction has not yet been translated into permanent histologic tissue change. The era of bacterial supremacy in disease concepts appears to be giving way to a realization that intrinsic bodily dysfunction in the neurovascular, neurosecretory and neuromuscular mechanisms may be of more importance in many previously obscure disorders than the presence of bacteria of dubious pathogenicity. The focal disease theory shrinks into relative insignificance as one bodily disorder after another, previously ascribed to it, is demonstrated to result from autonomic dysfunction. The emphasis of recent years on psychosomatic medicine is an expression of general medical awareness of the impact of man's environment on a neural mechanism which may not be equal to a smooth performance of its task.

The inner ear is a structure well-designed anatomically to give gross symptomatic expression to very minor alterations in its neurovascular and, perhaps, neurosecretory mechanisms. Few end organs in the body are as expressive of minute changes in autonomic control. It is a rigidly closed space. Circulation is supplied by an end artery and its branches. Collateral circulation is absent. The neural mechanisms dependent on this arterial supply are minute and delicate. Extremely fine vascular change results in relatively severe subjective sensory disturbance. These may be of an acoustic nature, a static nature, or both, dependent upon the arterial branch involved. The main artery is the internal auditory, a branch of the basilar. Its ramifications supply all parts of the labyrinth. A noteworthy branch, the vestibulocochlear artery, carries blood to the basal turn of the cochlea and to a portion of the saccule, utricle and posterior ampulla of the vestibule. Involvements of cochlear branches give tinnitus and produce hearing impairment when long continued. Vestibular branch changes alter one's sense of position in space. Dependent upon the degree of vascular change, this alteration may be minor, resulting in purely subjective symptoms or of more severe degree and manifested by the objective signs of nystagmus, falling, and past pointing. The subjective sensation of minor vestibular involvement need not be that of violent pulsion or of rotatory movement. When it is neither of these, its evaluation may be difficult, because it is purely subjective. It may, however, be evidence of the earliest functional vascular change in the vestibule. When the vestibulo-cochlear artery is affected, high tone tinnitus and vestibular imbalance are combined symptomatically. Major involvement of the internal auditory artery gives extraordinary subjective tinnitus in all frequencies and completely disrupts the patient's orientation in space.

The changes in neurovascular tonus in the inner ear may be precipitate and extreme or they may be of minor degree and long continued. The cataclysmic disorder of major vascular involvment was organized into a syn-

drome by the writings of Ménière. The chronic progressive degeneration of long continued minor neurovascular change has been obscured as catarrhal deafness or primary eighth nerve neuritis, for several medical generations. The altered physiology producing both pictures differs not in character but in degree. The autonomic nerve distribution which controls them has received little medical thought, though the clinical picture which results has filled medical volumes.

The autonomic nervous system is a motor mechanism comprised in reality of two opposed systems which maintain the equilibrium of the organism's adjustment to its environment—the one is the sympathetic system, the other the parasympathetic. Sympathetic innervation of the labyrinth arises from the thoracic cord and extends cephalad in the cervical sympathetic trunk and its continuation, the internal carotid nerve. The inferior carotico-tympanic branch of the latter traverses the bony septum between the carotid canal and middle ear. It is here joined by a branch of the ninth cranial nerve and the ramifications of the two on the promontory of the middle ear are termed the tympanic plexus. The tympano-sympathectomy of Lempert for intractable tinnitus is based on the destruction of this plexus through an external auditory canal approach which is accomplished by temporarily displacing the tympanic membrane. This sympathetic ablation may not be complete, however, and thus may miss its clinical goal due to possible additional sympathetic innervation of the inner ear through carotid plexus fibers which do not traverse the middle ear but reach the seventh nerve through other anastomosis, as of the deep petrosal nerve with the great superficial petrosal.

The tympanic nerve which emerges from the tympanic plexus traverses the middle fossa surface of the petrous portion of the temporal bone as the lesser superficial petrosal nerve. By connections of the latter with the geniculate ganglion, as well as by direct connecting fibers from the tympanic plexus to the geniculate ganglion and seventh nerve, sympathetic fibers from the cervical trunk and possible parasympathetic fibers from the ninth cranial nerve reach the seventh. The eighth nerve, or cochleo-vestibular nerve, carries no autonomic nerve, fibers from the brain stem. Yet, as shown by Lorente de No, this nerve does have such fibers when it ramifies to the cochlear and vestibular end organs in the fundus of the internal auditory canal. The connecting nerve filament which carries these autonomic fibers from the seventh to the eighth cranial nerve in their course in the internal auditory canal was demonstrated by de No in 1925. It completes the anatomic basis for the neurovascular syndrome of the inner ear.

There is little known about the effect of increased parasympathetic tonus in the inner ear. It is possible that it controls neurovascular phenomena through vasodilator activity and produces common clinical pictures. The usual experimental study has been done not by stimulation of the parasympathetic as a dynamic vasodilating force, but rather by destruction of the sympathetic innervation to produce that effect passively. Direct sympethetic stimulation has been carried out repeatedly. A mass of experimental work has followed three general lines:

1. Cervical sympathectomy and stimulation of the sympathetic at the cervical trunk or below.

2. The effects of drugs acting on the sympathetic system.

3. The results of operations on man with and without ear disease.

Fraser has summarized the work:

"The results are somewhat conflicting but the conclusion which emerges is as follows: constriction of the labyrinthine vessels leads to an increase in the excitability of the vestibule. Dilatation of these vessels leads to a diminution in the excitability of the vestibule with an increase in the acuity of hearing."

An additional physiologic effect in the inner ear is possible through autonomic stimulation. Increased neurosecretory activity through parasympathetic stimulation is possible. Shambaugh, Sr., in his work on the inner ear demonstrated to his own satisfaction that true secretory activity exists in the external sulcus cells of the cochlear duct. By correlation with other secretory mechanisms of the body, this activity should imply parasympathetic innervation. However, the onset of tinnitus or vertigo is sometimes so sudden and violent that it is hard to visualize it as based on sudden increase in neurosecretory activity alone.

Thus there is abundant experimental and clinical evidence that neurovascular changes in the inner ear occur through disturbance of the autonomic innervation. And there are some evidences that neurosecretory mechanisms exist which, in some instances, can contribute to the change in the inner ear. The clinical results in complaints of tinnitus, hearing impairment and vertigo, may be large for the degree of change involved because the inner ear is a rigidly closed space, and the contained neural elements are of extreme sensitivity.

One inherits his autonomic nervous system. If it be an unstable one, the potentiality toward certain clinical disorders is great. The impact of the environment results in manifestations of autonomic imbalance in many body systems. The mechanism is sometimes set in motion by single, specific effectors, such as foods, or inhalant substances, and the body system involved becomes established as a shock organ which thereafter may react to those substances independent of central neural controls. The clinical picture of allergy results. Often, and particularly in a vigorous climate, physical factors of temperature and humidity and their rapid alteration will produce striking autonomic effects. The result has been spoken of as physical allergy and sometimes as intrinsic allergy. There remains yet another effector, and more important perhaps than extrinsic food, inhalant or physical factors, which can produce marked clinical disorder through autonomic disturbance. That effector is the individual's own emotion. This factor brings confusion to the ordinary concepts of allergy. It is the effector in a high percentage of the intractable, or fixed, allergic reactions.

Autonomic dysfunction in the inner ear comes under the influence of these effectors. These factors operate particularly effectively upon a familially unstable autonomic system. In the same individual, one or all may be capable of producing the clinical syndrome of the inner ear. Foods and inhalants are of least importance. The inner ear is not commonly their shock organ. The individual who develops tinnitus, vertigo and hearing impairment from a specific food or inhalant is uncommon enough to be worthy of remark. Physical factors have more significance. Tinnitus is more commonly noted during periods of inclement weather and changes of season. Vestibular vertigo, with or without cochlear symptoms, is more frequently seen during the same periods. These, however, are observations that are difficult to demonstrate statistically because the individual who is truly physically sensitive is usually also most subject to emotional effects through the same autonomic mechanism, and emotional stress knows no season.

Williams deserves great credit for organizing the many autonomic imbalances of the head into the picture of intrinsic allergy of the head. One patient may manifest neurovascular and neurosecretory changes in many systems. In the head, Williams has grouped these into myalgias, vasodilating pains, chronic vasomotor rhinitis and endolymphatic hydrops. In his experience, 23 per cent of patients with endolymphatic hydrops had associated symptoms in the other fields. This is a conservative figure. In our experience it has been nearer 75 per cent when we include the patient with early symptoms of vasomotor labyrinthitis, as well as the patient in the advanced stage.

The terminology of the inner ear syndrome is confusing. It has run the gamut from Ménière's disease to endolymphatic hydrops. In order that all degrees of autonomic dysfunction in the inner ear be given a common etiologic diagnostic term, it would seem preferable to denote the disturbance as vasomotor labyrinthitis where all components of the inner ear are involved, and vasomotor cochleariti s or vasomotor vestibulitis where only acoustic or only static components have yet been involved. Gross disorder involves vestibule and cochlea and results in a syndrome pathognomonic of inner ear disease. It includes violent tinnitus and hearing impairment, severe vertigo, nausea and vomiting. Careful history demonstrates that in over 80 per cent of patients a premonitory phase precedes the first violent inner ear attack. This phase may last for years and be characterized only by intermittent tinnitis, with or without gradually developing hearing impairment, or by mild, transient vertigo, elicited only by abrupt positional change. These symptoms are evidences of poor autonomic adjustments in the neurovascular control of the inner ear. At this stage of the disorder the majority of patients will evidence other symptoms of cranial autonomic instability in the form of myalgia, vasodilating pain, or chronic vasomotor rhinitis, or in a positive family history of similar parental or sibling involvement. In fact, the associated vasomotor rhinitis and pain phenomena have been so commonly noted in association with these ear symptoms in past decades, that the misnomer of catarrhal deafness became descriptive of the chronic progressive cochlear degeneration which resulted. The misept practice of auditory tubal inflation became a standard otologic procedure. It is embarrassing to reflect today on the hundreds of thousands of middle ear inflations which have been doggedly indulged in, in an effort to relieve by aerodynamics a disorder which in reality results from nerovascular disturbance in the inner ear.

Most patients with inner ear symptoms from faulty autonomic balance never manifest the complete syndrome of inner ear disruption. All are potential candidates, however. The first appearance of tinnitus or of vertigo on quick alteration of position in a patient with associated evidence of autonomic imbalance, or a pronounced family history of same, marks the individual in the astute clinician's mind. It is interesting to follow the vasomotor vagaries of one such individual for several years and see the first complete inner ear syndrome appear suddenly and cataclysmically after a particularly severe environmental stress. For every individual who progresses to this point there are scores who continue for years with lesser involvments. When the latter concern vestibular arterial branches only, the pseudo-Ménière's syndrome of Dandy or vasomotor vestibulitis is noted in varying degrees of severity. When cochlear arterial segments alone are involved, the vasomotor cochleariti s results in intermittent or constant tinnitus and progressive and permanent inner ear type hearing impairment. If the vestibulo-cochlear artery from the internal auditory is affected, it is reasonable to expect tinnitus of high pitch, high tone impairment and variable vertigo.

The pathological change in the inner ear which results from vascular alteration could conceivably take two forms; that resulting from frequent minor changes in vessel lumen, and that resulting from sudden major alteration in circulation. These may differ not at all in mechanism of production but only in degree of involvement. Relative to the former, the observations of Guild on the pathology of chronic progressive inner ear deafness are of moment. He states:

> "Normal-looking blood vessels are present in our sections in regions with total atrophy of the organ of Corti. The fact that the areas of end-organ atrophy are often very sharply circumscribed suggests occlusion of terminal arteries as the cause; we have no histological evidence, however, to support this view. The clinical and pathological evidences of systemic vascular disease, as recorded in our tables, also indicate that arteriosclerosis or arteriolosclerosis is not the cause of organ of Corti atrophy."

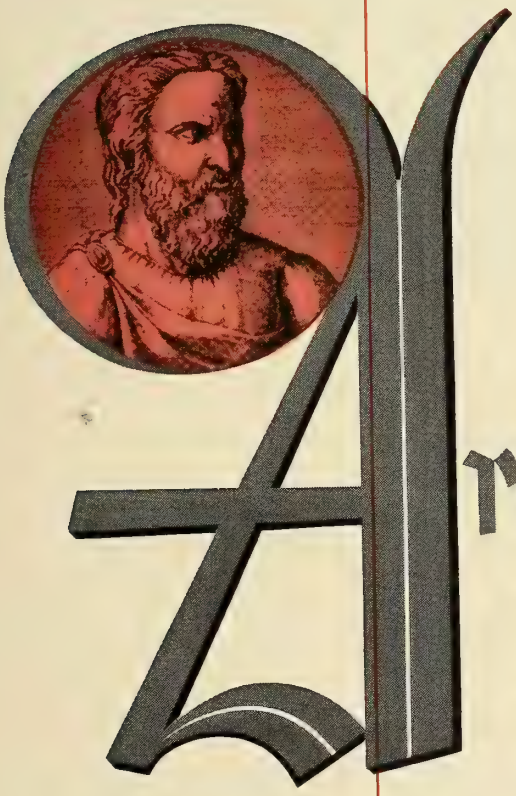
It is probable that recurrent and transient alterations in vessel lumen produce the permanent neural damage without histologically demonstrable vessel change.

At the other end of the scale of neurovascular change, the pathology of the complete inner ear syndrome with violent clinical manifestations in acoustic and static spheres was shown first by Hallpike and Cairns and since corroborated by Lindsay and many others. They

have shown a gross dilatation of the endolymphatic system with destruction of the neural elements. It can only have resulted from transudation and edema originating probably from the stria vascularis or from hypersecretion, perhaps from the external sulcus cells of Shambaugh.

By what mechanism of the autonomic innervation are these vascular and possibly secretory effects produced? Is it by dynamic activity of the sympathetic segment with the production of vasospasm? Or is it by rigorous overactivity of the parasympathetic with forceful vasodilation and active secretory stimulation? Williams, two years ago, called attention to the work of Otfried Muller in Switzerland who, "described an inherited tendency for capillary loops to behave in an abnormal manner on exposure of the organism to physical and emotional stimuli." Vasospasm impedes the flow of blood through the capillary loops, and endothelial damage with transudation and edema results. This vasospasm may be an expression of sympathetic overactivity. Therapeutic response to vasodilating drugs lends support to their viewpoint. Furthermore, there is no conclusive experimental evidence that parasympathetic vasodilator activity exists in the inner ear.

Modern drug therapy in vasomotor cochleariti, vasomotor vestibulitis and vasomotor labyrinthitis, in either the acute or chronic form, aims at re-establishing the integrity of the inner ear circulation. The forceful vasodilation of intravenous histamine, used in constant drip or intermittent daily injection, is probably most purposeful in the acute stage of severe vascular involvement. In the past year we have alternated its use with that of intravenous tetraethylammonium chloride. The transient autonomic block at ganglion level produced by this drug can terminate an acute, severe vasomotor labyrinthine attack. Its use has gone far to clarify our thinking on the influence of the autonomic system in producing severe vasodilating pains about the head, as well as its role in the violent episodes of the inner ear. We are still broadening our experience with it and here offer its use as therapeutic evidence of autonomic influence in vasomtor labyrinthitis. We believe it will have a place in accepted therapy. Nicotinic acid is also used for its vasodilating influence. When used in frequently repeated doses over long periods of time, it affords the most useful long-term control measure available today. The local neural block effected by the misnamed antihistamine drugs can in an occasional case correct the vasomotor dysfunction when used symptomtatically.



The commonest error in therapy is the tendency to guide it by the response of the patient's vertigo. Horton first accented the patient's hearing as the best indicator of adequate treatment, particularly in the acute vasomotor disturbances. Treatment must be continued until maximum cochlear return has been effected. The patient may have no further vertigo long before this stage. The cochlea is a more delicate mechanism than the vestibule. Oft-repeated vascular damage is cumulative and irreversible in it. It must be reversed shortly after the onset of symptoms by vigorous therapy, or an additional increment of hearing loss will be permanent. The audiometer is essential as a gauge of acuity. Voice tests are inadequate. They are neither accurate nor do they test the high frequencies usually most severely involved.

Some systemic factors have been noted repeatedly to have an influence on the production of inner ear symptoms through autonomic mediation. In the treatment of the disorder they should be given proper attention as contributors only. Endocrine factors in women which influence vasomotor control during the menopause, or at the time of the menstrual period, accent vertigo and tinnitus in the autonomic unstable individual during those periods. The low metabolic rate commonly found in both males and females with autonomic instability need not be a cause of their inner ear symptoms but rather another result of faulty autonomic regulation. The use of thyroid, therefore, should not be viewed as a complete method of treatment but as an adjunct only. The influence of fatigue and tobacco in the production of vasospasm makes adequate rest and abstinence from smoking one of the first rules of proper therapy.

Drug therapy has distinct limitations in a disorder in which emotional factors play a major etiologic role. The patient with early and still tractable vasomotor irregularity in his labryinth often needs correction in his attitude toward life. Drug therapy serves best in the acute severe phase of vasomotor change. Psychotherapy is frequently more important in maintaining stability once regained.

The patient with far advanced vasomotor labyrinthitis usually has permanent loss of useful hearing in the involved side with a vestibular mechanism still sufficiently viable to repeatedly disable him with attacks of vertigo. Often his abnormal neurovascular habit is so deeply rooted that it responds poorly, if at all, to medical and psychiatric correction. The number of advanced cases comprises an extremely small percentage of the total with vasomotor labryinthine disease. With early recognition and proper medical and psychiatric treatment, this small percentage will dwindle further. Surgical destruction of the involved labryinth is the only control measure one can at present offer the intractable case. Dandy accomplished this with differential intracranial section of the eighth nerve. Today, that quite formidable procedure is utilized only for cases with disabling and uncontrollable vertigo who have retained good cochlear function, or in cases with bilateral vestibular involvement. These are uncommon. The labryinthotomy procedure of Day has largely replaced intracranial section. It is accomplished through a mastoid approach to the lateral semi-circular canal and is a procedure with little morbidity. It now appears that a technique elaborated by Lempert may even be preferable to that of Day. It is effected through the external auditory canal. The drum head is temporarily displaced so as to expose the medial wall of the middle ear; the incus is sectioned, thus freeing the stapes from the ossicular chain; the stapes and oval window membrane are then removed and the round window membrane perforated; the drum head is replaced. Morbidity is minimal, and postoperative vertigo is dependent only on the

amount of vestibular activity present preoperatively, as evidenced by the caloric test.

With either the Day or Lempert procedures, residual hearing is lost on the involved side. For that reason, this operation is reserved for disabled and uncontrollable cases with no useful hearing remaining on the involved side. The possibility of opposite side involvement in so general a disorder as vasomotor instability exists. The sacrifice of useful hearing could be disastrous if, in the future, vasomotor cochlearitis developed in the opposite ear.

The use of streptomycin by intramuscular injection to destroy the vestibular end organ by selective neurotoxic action is receiving wide attention. It is possible that its usage should be limited until its neurotoxicity is conclusively shown to exist for the vestibular end organ alone. An infrequent case of vasomotor vestibulitis may suffer severe and disabling vertigo, yet show no cochlear component to help in lateralizing the disorder. Here, differential section of the eighth nerve is not applicable because the side producing vertigo may not be definitely determinable. Labyrinthotomy is not applicable because useful hearing would be destroyed. Streptomycin destruction of both vestibules would seem reasonable in such an instance.

Summary

The syndrome of the inner ear results from neurovascular, and possibly neurosecretory, change in the labryinth.

This change may be acute and severe, as the result of sudden alteration in the vascular tonus of large segments of the neural mechanisms of the inner ear, and produce the picture of severe acute vasomotor labyrinthitis, vasomotor cochlearitis, or vasomotor vestibulitis; or it may be chronic and insidious, as the result of long continued and intermittent alterations in the vascular tonus of many small segments of the neural mechanism of the inner ear, and result in chronic vasomotor labyrinthitis, vasomotor cochlearitis, or vasomotor vestibulitis.

These changes are mediated by autonomic mechanisms which differ not in kind but in degree.

They occur most frequently in individuals with inherited autonomic instability.

The majority of these individuals manifest evidences of autonomic dysfunction in other body systems.

Extrinsic physical factors and intrinsic emotional stress are the commonest precipitors of autonomic dysfunction in the labryinth.

Proper medical and psychiatric treatment can relieve and control many of the vasomotor disorders of the inner ear.

A small percentage require surgical destruction of labryinthine components because of intractable autonomic dysfunction.

Discussion

DR. L. R. BOIES, Minneapolis: It has been suggested that the first paper on this evening's program might be a bit over our heads. The same thought occurs to me in regard to Dr. Hilger's thesis. Nevertheless, his thinking is probably in the vanguard of thought which will explain some things which have not been satisfactorily explained by our clinical experience to date.

Dr. Hilger remarked that "the focal disease theory shrinks into relative insignificance as one bodily disorder after another, previously ascribed to it, is demonstrated to result from autonomic dysfunction." Probably no area in the body has been searched more diligently for a source of infection to impair bodily function than has the field of activity of the otolaryngologist. And it is a fact that the activities of modern rhinologists have decreased at least 50 per cent in the matter of focal disease.

Another activity which has undergone a change in our specialty has been the correction of supposed nasal pathologic conditions to cure chronic headache. It is now known that in most victims of a headache which is a chronic problem, "sinus disease" or other nasal pathology is not the common cause, but the headache is often related to some autonomic dysfunction which alters normal vascular physiology.

I have been stimulated by Dr. Hilger's presentation, and I thank him for it.

DR. C. E. CONNOR, Saint Paul: I have no comment on the technical content of the paper; it covers the field very adequately. There is one thing I would like to say, however. Dr. Hilger said that in the past there have been many aspects of otology which have appeared hopeless and in which we have had nothing to offer in the way of treatment; many patients have observed, "When are you otologists ever going to make any progress in your field?"

I think some progress has been made in the last decade or two. New knowledge in physiology, in biochemistry, in acoustics and electronics, is being brought to bear on many obscure conditions. There are new techniques in the approach to otological problems; Crowe, at Hopkins, and others have done much work in which antemortem studies of cochlear function are correlated with postmortem pathological examinations. The combination of new knowledge in other fields and new methods of study in otology are beginning to yield tangible results.

DR. HILGER, in closing: I want to thank Dr. Boies and Dr. Connor. Certainly the basis of our advances in the last ten years is physiology. Many of the things that one feels will be definitely demonstrated in the next few years as fact are now in the formative stage of part fact and part theory. In treatment, I think more emphasis must be placed on psychotherapy than has been the trend in the past. Our Fellows in otolaryngology at the University cannot fully appreciate it now, but the changes in our field have been very great in the past ten years. We have become much less mechanical minded and much more physiologic.

The meeting adjourned.

Communication

To The Editor:

A letter written by Dr. Kano Ikeda appeared in the January, 1948, issue of MINNESOTA MEDICINE stating the objections of the clinical pathologists to a resolution unanimously passed by the House of Delegates of the Minnesota Medical Association in July 1947, petitioning the Minnesota State Board of Health to include routine RH typing in its laboratory service. As the one who presented this matter to the Minnesota Society of Obstetrics and Gynecology at its meeting during May 1947 in Duluth, at which time a resolution was unanimously approved requesting the House of Delegates of the Minnesota Medical Association to petition the Minnesota Board of Health to include the above services in its laboratory, I would like to present a different point of view.

With the introduction of the RH and AB factors as a cause of erythroblastosis a problem comparable to the Wassermann problem of some decades ago has been created. Then as now with blood typing, private facilities for doing Wassermann tests were well established and available, but unfortunately were not generally utilized as a routine, especially during pregnancy. Syphilis being a communicable disease there is no longer any question that its recognition through Wassermann testing is a public health function. Although RH and ABO factors are in a different category, disasters due to the omission of blood typing may well be considered public health problems. Among these, erythroblastosis especially engages the attention of the pediatrician and obstetrician. It is now well established that the RH negative mother of an erythroblastotic baby with the RH positive homozygous husband will continue to have erythroblastotic babies. The same is true with the A and B factors but the incidence is much less frequent. Consequently, although the latter may be involved in similar situations, this discussion will be limited to the problems involving the RH factor. At the present time the most hopeful manner in which the presumptive erythroblastotic baby can be treated as through the possible early induction of labor followed by an exchange transfusion of the infant with RH negative blood. This in turn necessitates definite knowledge of the RH status of a woman early in pregnancy. Because RH typing in the pregnant woman in spite of the existing facilities is now for the most part being omitted it would seem desirable for the State Board of Health to take over and exploit the procedure at least in this group. The same specimen of blood drawn for the Wassermann test could easily be used for RH blood typing.

At the moment this would appear to be of some disadvantage to the clinical pathologist, but will it not eventually result in more work for him? First, because once it has been established that the pregnant woman is

MAY-O-LITE Helps Your Patients . . . Enjoy Their Glasses

If glasses are prescribed, they should be worn. However, often glasses are laid aside and not worn because of some hard to explain "bother," which is in most cases reflection on the lenses.

Recently, a high school girl was fitted with her first pair of glasses. After a few days, she laid them aside because they didn't seem right . . . they "bothered" her. Later, when she told her doctor that she could "see things" in them, he suggested May-O-Lite coating. Not long after that the young lady called him on the phone, exclaiming, "Now I can wear my glasses anywhere, in school, on the street . . . and those 'things' just aren't there."

MAY-O-LITE Low Reflection Lens Treatment reduces surface reflection from 80 to 95%.

Besides reducing surface reflection and minimizing eye strain, MAY-O-LITE improves image definition. MAY-O-LITE Low Reflection Lens Coating is available through your manufacturing and dispensing optician. Write for a descriptive pamphlet and a treated sample of glass, today.

MAY RESEARCH

Minneapolis 1, Minnesota

RH negative it is incumbent upon the attending physician to ascertain not only the RH status, but the heterozygocity and the homozygocity of the husband. Secondly, when it has been settled that a pregnant woman is RH negative and the husband is RH positive, it then becomes the duty of the attending physician to determine whether or not iso-immunization is developing in the prospective mother. Such determinations could not be handled in the laboratories of the State Board of Health and would necessitate the utilization of the facilities of the various clinical pathologists. It is not the aim of the leaders in this movement to have the State Board of Health establish a complete hematological laboratory. Only routine RH and ABO typing would be done, because the equipment necessary for the determination and titration of RH and AB iso-immunization is quite beyond the budget limits of the Board of Health.

Generally the public is not inclined to pay for what it regards as unnecessary services. Rather an attitude prevails of, "It can't happen to me." However, once the seriousness of a given medical situation is revealed, cost means little.

Potentually, every RH negative woman with the RH positive husband is confronted with a serious situation if she becomes pregnant. Even though in the minority, with those who are destined to have an erythroblastotic baby due to RH sensitization, the only hope for even one surviving child may be in the early recognition and the subsequent titration course of the iso-immunization. Erythroblastosis is more lethal than congenital syphilis and much less amenable to treatment. Public attitudes then being what they are, it would seem not only desirable but logical for the State Board of Health to undertake the routine typing for the RH factor.

No physician would wish to establish an agency detrimental to any member of the medical profession. If routine RH and ABO typing by the Minnesota State Board of Health would seriously handicap the clinical pathologists it would be one thing, but if its exploitation potentially adds to his benefits it is quite another. Controversy as to the principle involved becomes trivial. Even if this were untrue Medicine must maintain that human problems transcend limited interests of the individual.

In conclusion, routine RH typing by the State Board of Health in Minnesota would be no innovation. As of January 1947, the Boards of Health in seven states, Massachusetts, Vermont, Georgia, South Dakota, Nebraska, Florida, and Connecticut do routine RH typing. In eleven states, California, New York, New Jersey, Wyoming, Michigan, Idaho, South Carolina, Ohio, Rhode Island, Kentucky and Wisconsin RH typing is done by the Boards of Health on request. In three of the above named states determinations and titrations of iso-immunizations are a function of the Health Boards Laboratories.

May I urge the Council of the Minnesota Medical Association to act immediately on the petition of its House of Delegates.

Yours truly,
C. J. EHRENBERG, M.D.

In Memoriam

CHRISTIAN FREDERICK CARSTENS

Dr. C. F. Carstens, a practitioner at Hibbing, Minnesota, since 1914, died on February 19, 1948. He was sixty-eight years old and had been disabled since November, 1942.

He was born in Ackley, Iowa, October 7, 1879. He attended Lake Forest Academy and Lake Forest College at Lake Forest, Illinois. After graduating from college he taught school in the Philippines for three years. In 1904, he returned to this country and studied medicine at Johns Hopkins, where he graduated in 1908.

Dr. Carstens joined the staff of the Rood Hospital in 1910, serving for four years in Keewatin before moving to Hibbing in 1914. During World War I, he served in the medical officers training camp at Fort Riley. In 1941, he helped form the Mesaba Clinic at Hibbing.

He was a member of the St. Louis County Medical Society, the Minnesota State and American Medical Associations. He was also a member of the Mesaba Lodge of Masons, the Chamber of Commerce, the Mesaba Country Club, and the Algonquin Club. He had served as chief of staff of the Hibbing General Hospital and as a director of the Children's Home Society of Saint Paul. He was a member of the Presbyterian church.

Dr. Carstens is survived by his widow, Lucile, and a daughter, Caroline, who is attending Stephens College, at Columbia, Missouri.

THEODORE F. HAMMERMEISTER

Dr. Theodore F. Hammermeister, well known surgeon of New Ulm, died February 14, 1948, of a heart attack.

He was born at Morgan in Eden township, Minnesota, July 25, 1887. He obtained his medical degree from the University of Minnesota in 1914 and interned at Northwestern Hospital, and at the University Hospital, Minneapolis.

In June, 1915, Dr. Hammermeister went to New Ulm, where he associated with the late Dr. O. C. Strickler until 1918, when he opened an office of his own. In 1926, he went into partnership with Dr. C. A. Saffert.

He was a member of the Redwood Brown Medical Society, the Minnesota State and American Medical Associations. He was also a member of the Southern Minnesota Medical Association. Interested in education, he served many years as a member of the New Ulm school board and as president of the board. For ten years, he was health officer of New Ulm.

Dr. Hammermeister married Isobelle M. Dunn on June 8, 1915. Mrs. Hammermeister died in 1933. A son, Robert, now lives in Minneapolis. In 1935, Dr. Hammermeister married Mrs. Pearl Rexford, who survives him.

HAWLEY S. SANFORD

Dr. Hawley S. Sanford, son of Dr. and Mrs. A. H. Sanford of Rochester, died February 24, 1948, in Detroit, Michigan, of acute coronary disease.

He was born in Milwaukee, January 24, 1909. He attended public schools in Rochester and received his M.D. from Harvard Medical School in 1933. Interning at the George F. Geisinger Memorial Hospital in Danville, Pennsylvania, he entered the Mayo Foundation as a fellow in surgery in 1934. Later, he changed his major subject to neurology and received the degree of M. S. in neurology and psychiatry from the University of Minnesota in 1937. At this time, he went to Detroit, where he was neuropsychiatrist on the staff of the Henry Ford Hospital. He served as a major in the Army Air Force in World War II.

Besides his parents, Dr. Sanford is survived by his wife, a son and daughter, and a brother, Dr. Raymond A. Sanford of Rochester.

DE COSTA RHINES

Dr. De Costa Rhines, formerly of Caledonia, died at the home of his daughter, Mrs. Hazel L. Hosfield in Owatonna, Minnesota, on February 9, 1948, at the age of ninety-five.

Dr. Rhines was born January 18, 1853, in Jackson County, Michigan. He graduated from the Hahnemann Medical College at Chicago in 1884 and began practice at River Junction, Michigan. After changing his location to Houston County, Michigan, he moved to Caledonia in 1899. Here he practiced until his retirement several years ago. In 1941, he and Mrs. Rhines moved to Owatonna to make their home with their daughter.

He was a former member of the Houston-Fillmore County Medical Society, the Minnesota State and American Medical Associations. He served for many years as county coroner, a term as president of the village council and on the school board. He was also a past master of the Caledonia Masonic lodge.

Since moving to Owatonna, Mrs. Rhines passed away. Dr. Rhines is survived by one daughter, Mrs. Hosfield, and one son, Ray N. Rhines of Burlington, Washington.

Dr. Rhines' practice of over fifty years extended back to the horse and buggy days and represented years of devotion to his patients and country.

AARON FRANKLIN SCHMITT

Dr. Aaron F. Schmitt, a surgeon of Mankato until his retirement from practice in June, 1921, passed away March 15, 1948, at his home in Minneapolis, at the age of seventy-eight. He suffered a coronary occlusion on June 5, 1925 and a stroke in August, 1925, with resulting hemiplegia.

Dr. Schmitt was born in New Trier, Dakota County, Minnesota, February 12, 1870. He attended high school in Mankato. His M. D. was obtained from Rush Medical College in 1902. He practiced at Wells, Minnesota, from 1901 to 1906 and at Mankato from 1906 to 1921. In 1910

he took postgraduate work at Berlin, Vienna, London, and Leeds.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations. For a number of years, as chairman of the Program Committee of the Southern Minnesota Medical Association, he was the dynamic force which brought the association into prominence. He was a member of the American College of Surgeons and a former member of the Minnesota State Board of Medical Examiners. He was also a member of the Scottish Rite and the Osman Shrine.

Dr. Schmitt is survived by his wife, two daughters—Mrs. E. C. Merrill of Harrah, Washington, and Mrs. Harold Habein of Rochester, two sisters—Mrs. David Kienholz of Stanley, Wisconsin, and Mrs. Frank Bailey of Pittsburgh, and two brothers—George Schmitt of Madison and Dr. Samuel C. Schmitt of San Diego, California.

ROBERT OTTO MEYER

December 12, 1947, marked the passing of one of the great leaders in contemporary Medicine, Dr. Robert Otto Meyer. His death in his eighty-third year occurred in Minneapolis, Minnesota, where he lived after his exile from Germany in 1939. Inasmuch as his biography has been well chronicled, another is superfluous. Dr. Emil Novak of Baltimore presented the first in an address before the sixty-ninth annual meeting of the American Gynecological Society, entitled "The Life and Works of Robert Meyer." This address was published in the *American Journal of Obstetrics and Gynecology* of January, 1947. Secondly, Dr. Meyer's autobiography is currently being published as a serial in the *Journal of the History of Medicine and Allied Sciences,* which is later to be presented in book form.

Dr. Meyer was a cultured European scholar and scientist. He was a true aristocrat through the humble appreciation of his own knowledge and attainments, of which he could not be deprived but which were never flaunted. Born to moderate wealth during a peaceful and prosperous era in German history, he was destined to experience increasing material adversities through World War I, the Hitler regime, and World War II. In spite of all this, he never expressed resentment or indignation. Instead, events in his life were historical incidents that he wove into a systematic pattern in which he was never the victim but always the master. In his own words taken from his autobiography which was written in his last years, "I have had an exceedingly beautiful life which would be worth living once more. I have always had the feeling in difficult situations that things would come out well, and they came out right. I let life approach me, made my decisions and they were right."

One could not be in his presence for long without feeling his consummate kindliness, a quality made more gracious by its simplicity, sincerity and dignity. An authority, he was never the austere master, but rather the sympathetic colleague. No problem was so simple that it could not be followed to its end. On the other

DRINK
Coca-Cola
TRADE MARK REG.

You trust
its quality

hand, with more complex problems, well-chosen questions invariably led on to greater clarification or solution. His knowledge was precise, well-defined and usually philosophical. An example of this was his definition of menstruation. "It is a cyclic uterine bleeding, occurring ideally every twenty-eight days, preceded by ovulation, corpus luteum formation and a secretory endometrium." These requisites implied the possibility of pregnancy. Consequently, the term "anovulatory menstruation" of Corner, Hartman, Novak and others, although a cyclic uterine bleeding but from a proliferative endometrium, was conclusively in Dr. Meyer's mind a misnomer, confusing and philosophically incorrect. Menstruation traditionally was related to reproduction and pregnancy, so obviously an anovulatory uterine bleeding, although cyclic, physiologic, and probably normal to the human female at times in her menstrual life must be defined as such. A precise concept was necessary for thinking properly in a scientific realm.

His microscopy is worthy of mention. He would spend from minutes to innumerable hours studying microscopic slides. After this the clinical history would be given, but only after the diagnosis had been made microscopically. If there was no agreement, then the whole was reviewed and reviewed again until a correlation was made. Through methods such as this, his monumental concepts were formed concerning, only to mention a few, the distinguishing characteristics of corpus luteum-endometrial relationships, hydatidiform mole and chorionepithelioma, and the various attributes of ovarian tumors. Many of these concepts are still recognized as his but others, accepted now as fact, no longer carry the connotation of his name. Although he was cognizant of this, he suffered no indignation. Rather, it was another manifestation of his true aristocratic character to know his contribution was an established truth. Whether the world recognized him or not made little difference.

Although the scientific attainments of Dr. Meyer were the factors in making him a world figure, he possessed others which contributed immeasurably to his stature. Unfortunately for him and his colleagues in Germany, he had no interest in politics. This was the function and concern of the politician, and as a man of science he would have none of it. Whether the course of German history would have been shaped differently had men of his proportions embraced politics will forever be an unanswered question. However, during his stay in the United States, he established his citizenry, a privilege in which he took pride.

Dr. Meyer was an expert in the field of philology. The study of Latin and Greek in his early years, especially the former, which he considered the most precise of all languages, provided the background. The precision of his written English was remarkable, although the spoken word was for him never without difficulty. On one occasion he took exception to the improper use of certain English words by an American colleague. During the subsequent controversy his knowledge of word derivation was such as to cause the retreating colleague to admit admiringly that it was expected of him to teach histology and embryology, but not English.

Dr. Meyer's philosophy extended far beyond the limits of his scientific thinking. Religion, literature, arts and music were to him of vital concern. Although a Jew racially, he was reared in the Lutheran Church. After maturity he confessed no creed, but his moral and religious convictions were profound and compelling.

His interest in and knowledge of literature transcended that of German origin. He was a keen student of Goethe, both from a literary and philosophical standpoint, but he was also thoroughly familiar with Shakespeare and could recite either with almost equal facility.

Quoting from Dr. Meyer's autobiography, "Music played a large role in my home town and in our home." He was privileged to have known Grieg intimately through his brother who played the piano with Grieg publicly. Further, he was familiar with Liszt, Brahms, Joachim, Saint-Saens, Clara Schumann and others, in that he heard and saw them many times. It was fascinating to hear him describe the contemporary and his own reaction to the first production of the works of Richard Wagner. During World War I, he was the organizer and leader of a symphony orchestra in a German base hospital in Brussels, of which he was a staff officer. This orchestra gave periodic concerts for the populace of Brussels. Although he enjoyed music, he maintained it was not high on the scale of human aptitude. Often he pointed out that musical prodigies were common when compared to those in science and mathematics.

Notwithstanding Dr. Meyer's intellectual accomplishments which made him at all times stimulating and instructive, there was more. He was human. The "common touch" was natural to him. He was equally affable as a guest or host. In the presence of women, he was courteous to the point of being gallant. Yet, in the presence of men he was natural even through the most risqué of stories. His wit was spontaneous and quick. Once when asked if food at a particular resort in which he had been a guest was "pretty good," he replied immediately, "Yes! pretty, but not good."

To have known him was a pleasant privilege, but also a prerogative that results in a deep sense of loss with his passing. Although the memory of his person will grow dimmer through the years, the truths which he established and stood for will shine out eternally, not only to us who knew him, but to posterity.

- Reports and Announcements -

AMERICAN ACADEMY OF PEDIATRICS

The Area Meeting of the American Academy of Pediatrics will be held at the Hotel Schroeder, Milwaukee, Wisconsin, June 28-30, 1948.

Members of State Medical Societies are welcome to attend. The registration fee will be $5.00 for such non-members, together with a $5.00 registration for which each registrant receives a ticket to the banquet, making a total registration fee of $10.00.

Registration may be made ahead of time by writing to Dr. C. G. Grulee, Secretary-Treasurer, American Academy of Pediatrics, 636 Church Street, Evanston, Illinois, enclosing a check for $10.00, or registration may be at the time of the meeting.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The Board of Examiners of the American College of Chest Physicians has announced that the next oral and written examinations for Fellowship will be held at Chicago on June 17. Candidates for Fellowship in the College, who would like to take the examinations, should contact the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

The fourteenth annual meeting of the College will be held at the Congress Hotel, Chicago, June 17 to 20. An interesting scientific program has been arranged for the meeting, and speakers from several other countries are scheduled to appear.

AMERICAN COLLEGE OF SURGEONS APPROVES USE OF NURSE ANESTHETISTS

The Board of Regents of the American College of Surgeons, at a meeting on February 22, 1948, adopted the following resolution:

The American College of Surgeons regards with deep concern the actions of some physician anesthesiologists in giving the impression to the laity in the public press that it is unsafe for experienced nurse anesthetists to conduct surgical anesthesia. While it supports the increasing tendency of having physician anesthesiologists in charge of surgical anesthesia, it deplores at this time any propaganda for the elimination of the trained nurse anesthetist. On the contrary, the American College of Surgeons is of the opinion that, in view of the inadequacy in number of the physician anesthesiologists and in view of the splendid record of achievement of the nurse anesthetists, institutions engaged in the training of nurses for this purpose should be encouraged to continue their programs.

AMERICAN HEARING SOCIETY

Beginning April 1, 1948, the American Hearing Society, which has been housed for twenty-five years in the Volta Bureau Building, 1537 35th Street, Northwest, will be occupying quarters at 817 14th Street, Northwest, Washington 5, D. C. Two factors influenced this move: an opportunity to secure a suite of offices (recently released by the government) on the fifth floor, with elevator service, in a downtown location, and a decision by the Board of Trustees of the Volta Bureau to remodel their building. Through telephone and personal contact, co-operation and co-ordination of efforts will continue between the two organizations, the Volta Bureau and the American Hearing Society.

NORTH DAKOTA STATE MEDICAL ASSOCIATION

The annual meeting of the North Dakota State Medical Association will be held at Jamestown, North Dakota, on May 23, 24 and 25. The scientific sessions will be held May 24 and 25. Members of the Minnesota State Medical Association are cordially invited to attend. Reservations may be made through the office of the North Dakota State Medical Association, Box 1198, Bismarck, North Dakota.

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL

Summer sessions for practicing physicians and medical students in the clinical and preclinical years will be held June 14 to 24 and July 26 to August 28. Courses both in the basic sciences and in clinical subjects will be offered.

The clinical facilities of the University Hospitals, Minneapolis General Hospital, Veterans Hospital and other affiliated hospitals of the medical school will be used, and clinical service will occupy approximately three-fourths of the time of those taking clinical subjects. This is an unusual opportunity for practicing physicians actually to work in these hospitals. Courses which are part of the regular medical curriculum will also be offered in the basic sciences and clinical subjects.

Further information may be obtained from the Dean of the Summer Session, 880 Administration Building, University of Minnesota, Minneapolis 14, Minnesota.

WASHINGTON COUNTY SOCIETY

At the regular meeting of the Washington County Medical Society, held in Stillwater on March 9, the principal speaker was Dr. C. W. Rogers, Minneapolis, who presented an x-ray illustrated lecture entitled "Diagnostic Difficulties in Urology."

During the business section of the meeting, action was taken on Dr. George McCue Ruggles' request for the society's approval of the Blue Cross plan for his hospital at Forest Lake.

Dr. John W. Stuhr, who had been hospitalized for a period following the fracturing of his left patella on January 18, was able to preside at the meeting. He had as his guest, Dr. S. W. Arhelger, who is studying under a fellowship in surgery at the University of Minnesota.

Of General Interest

Dr. Karl E. Johnson, Duluth, spoke on cancer control at a meeting of the West End Business and Civic Club in Duluth on March 16.

* * *

Formerly of the Veterans Hospital at St. Cloud, Dr. Rudolph B. Skogerboe in March opened an office for the general practice of medicine at Karlstad.

* * *

Members of the Blue Earth Valley Medical Society, meeting in Blue Earth on February 26, heard Dr. James W. DuShane of Rochester speak on "Congenital Heart Disease."

* * *

In Montreal, Quebec, at a meeting of the Montreal Neurological Society on March 10, Dr. L. M. Eaton of Rochester presented a talk and a motion picture demonstration on "Myasthenia Gravis."

* * *

At a meeting of the District of Columbia Medical Society, in Washington, D. C., on February 18, Dr. Philip S. Hench, Rochester, presented a paper entitled "Diagnosis and Treatment of Gout."

* * *

Medical aspects of atomic explosions were discussed by Dr. Hilbert Mark, Minneapolis, at a meeting on February 17 of army organized reserve medical units at Fort Snelling.

* * *

"Infections of the Urinary Tract" was the title of a paper presented by Dr. T. L. Pool, Rochester, at a meeting of the Urologic Section of the New York Academy of Medicine on February 18.

* * *

In behalf of the American Legion heart research professorship, Dr. B. C. Ford, Marshall, discussed rheumatic fever on a radio program broadcast over KMHL on February 12.

* * *

While Dr. B. W. Bunker of Anoka was in Florida with his family during part of February and March, his practice was maintained by Dr. Eugene Meyerding of Saint Paul.

* * *

On February 24 it was announced that Dr. Harvey J. Tompkins, formerly of the Veterans Hospital in St. Cloud, had been appointed chief of neuropsychiatry for the Veterans Administration.

* * *

Formerly of Minneapolis, Dr. Frederick M. Hass opened offices in Jordan about March 1 for the practice of medicine. After obtaining his medical degree, Dr. Hass served with the army occupation forces in Japan.

* * *

At a meeting of the American College of Allergists in New York City on March 14, Dr. B. T. Horton, Rochester, presented a paper written in collaboration with Dr. H. P. Wagener, entitled "Retrobulbar Neuritis; Treatment with Histamine."

* * *

Socialized medicine was discussed by Dr. E. M. Hammes, Saint Paul, in a talk on February 18 at a dinner meeting of the Saint Paul Business and Professional Women's Association.

* * *

Dr. John B. Erich, Rochester, at a sectional meeting of the American College of Surgeons in Denver, Colorado, during the first week of March, presented a paper entitled "Management of Traumatic Wounds about the Face."

* * *

Dr. William H. Bickel, Rochester, gave three lectures at the Lois Grunow Memorial Clinic in Phoenix, Arizona, about the middle of February. Subjects of his lectures were "The Differential Diagnosis of Foot Pain," "Backache," and "Treatment of Complications of Fractures."

* * *

"Anastomosis of Trachea with Polythene Tubes; An Experimental Study" was the title of a paper written by Dr. J. H. Grindlay and Dr. O. T. Clagett, Rochester, and presented by Dr. Grindlay at a meeting of the Central Surgical Association on February 19 in Chicago.

* * *

Chest clinics were conducted in Red Wing on February 24 and in Rochester on March 2 by Dr. Karl H. Pfuetze, superintendent of Mineral Springs Sanatorium, who examined ex-patients of the sanatorium and administered Mantoux tests to all persons desiring them.

* * *

Dr. Hilbert Mark, of the division of tuberculosis, Minnesota Department of Health, spoke on "Modern Aspects of Tuberculosis Control" at the forty-fourth annual midwinter council meeting of the Minnesota Federation of Women's Clubs, held in Minneapolis on February 20.

* * *

On the program at the meeting, to discuss the importance of immunization, were Dr. A. V. Stoesser, clinical professor of pediatrics at the University of Minnesota, and Dr. Clare Gates, director of health information of the Minneapolis Department of Health.

* * *

In Osakis it was announced on February 23 that Dr. E. E. Emerson had been named chairman of the local heart fund drive, part of the statewide campaign of the American Legion to establish a heart research professorship at the University of Minnesota.

* * *

At a meeting of the Colorado State Medical Society in Denver during the first week of March, Dr. G. J. Thompson, Rochester, presented two papers on urology.

They were entitled "Common Office Procedures in Urology" and "Diagnosis and Treatment of Tumors of the Bladder."

* * *

At the February 19 meeting of the Saint Paul Surgical Society, Dr. R. F. Hedin spoke on "Adrenal Tumors," and Dr. Grant Hartnagel was elected to membership in the society. Both physicians are associated with the Interstate Clinic of Red Wing.

* * *

In Shakopee about February 15, Dr. B. F. Pearson and Dr. Roy T. Pearson moved into newly decorated and refinished first-floor offices in the Hickman Building at 116 South Holmes Street. The physicians were formerly located in offices in the Shakopee Theatre Building.

* * *

Near the end of February, Dr. Louis B. Kucera joined his uncle, Dr. S. T. Kucera, in practice in the latter's office in Lonsdale. The younger Dr. Kucera is a graduate of Marquette College, Milwaukee, Wisconsin.

* * *

On February 28, Dr. W. H. Peterson began practice in Owatonna as an assistant to Dr. L. V. Berghs. A graduate of the University of Minnesota Medical School, Dr. Peterson interned at Sacramento County Hospital in California, then served for two years in the navy, from which he was discharged in December, 1947.

Dr. Donald Dukelow, director of the Health and Medical Care Division of the Minneapolis Council of Social Agencies, is sponsored by the University of Minnesota in his health broadcasts each Sunday at 11:15 a.m. over KUOM.

* * *

In St. Peter early in March, Dr. Alfred Sherman ended his partnership with Dr. Carleton S. Strathern and indicated that he might locate in another southern Minnesota city. Dr. Strathern planned to form a partnership with another physician as soon as business and living arrangements could be made.

* * *

In Cannon Falls during the first week of March, Dr. John B. Maunder became associated with Dr. M. R. Williams in the practice of medicine. A graduate of the University of Minnesota Medical School, Dr. Maunder was associated with a clinic at Milaca for a few years before moving to Cannon Falls.

* * *

After practicing for a year at Holdingford, Dr. Glenn Schmitz became associated in practice with Dr. A. E. Amundsen in Little Falls on March 1. A graduate of the University of St. Louis Medical School, Dr. Schmitz served his internship at a hospital in Wheeling, West Virginia. After being discharged from the army early in 1947, he began practice with his brother, Dr. E. J. Schmitz, in Holdingford.

In an address in Chicago early in March, greater study of the heart was urged by Dr. Ancel Keys, director of the University of Minnesota's laboratory of physiological hygiene, when he predicted that heart diseases will claim 1,200,000 persons a year in this country by 1960.

* * *

Recently appointed to the Minnesota State Board of Health and Vital Statistics, Dr. Theodore H. Sweetser, Minneapolis, replaced Dr. Erling S. Platou of Minneapolis, a board member since 1933. Dr. Ruth E. Boynton, also of Minneapolis, was reappointed to the board. The appointments were for three years each.

* * *

Four papers were presented by Dr. Louis A. Brunsting, Rochester, at a meeting of the New Orleans Graduate Medical Assembly in New Orleans during the last week of February. The papers were entitled "The Treatment of Psoriasis," "Recent Advances in Dermatology and Syphilology," "Hidradenitis Suppurativa," and "Early Recognition of Cancer."

* * *

Two Rochester physicians were on the program of the Cascade Farm Bureau when it met in the Rochester city hall on February 13. Dr. W. V. Leary discussed the x-ray survey being conducted in Olmsted County at the time, and Dr. C. G. Sutherland thanked members of the bureau for their support in the March of Dimes campaign.

* * *

Plans for setting up immunization clinics for children of school and preschool age were discussed at a citywide meeting of Minneapolis Parent-Teachers Association health chairmen on February 19. It was planned that the clinics would provide the initial immunization series for preschool children and booster doses for children already in school.

* * *

Speaking at a meeting in Worthington on February 11, Dr. F. L. Schade, president of the Southwestern Minnesota Medical Society, described suggestive signs and symptoms of cancer and pointed out that more than 170,000 persons in the United States died from cancer in 1947. The title of Dr. Schade's address was "Cancer, Its Detection, Diagnosis and Control."

* * *

Following his discharge from the army in December, 1947, Dr. P. M. Geiser settled in Alexandria on February 9 to become associated with the Alexandria Clinic. Dr. Geiser received a B.S. degree in medicine from the University of North Dakota and his M.D. degree from the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., in 1944. He served his internship and a residency at St. Mary's Hospital, Minneapolis.

* * *

In Deer River, Dr. A. L. Koskela and his brother, Dr. L. E. Koskela, assumed management and operation of the Deer River Community Hospital on March 1, as president and secretary, respectively. Dr. A. L. Koskela purchased the hospital building and clinic from Dr. G. A. Miners and Dr. H. R. Anderson in September, 1947.

* * *

After being affiliated with the Community Co-operative Health Center in Two Harbors since January 3, 1947, Dr. Ralph Papermaster presented the board of directors with his resignation on February 28, to be effective June 1. Dr. Papermaster announced that he will continue in private practice in Two Harbors, expecting to make his home permanently in the city.

* * *

Dr. J. J. Heisler has opened an office at 6224 Lyndale Avenue South, Richfield (Minneapolis suburb), where he is conducting a private practice in the afternoons. A staff physician at Minneapolis Veterans Hospital for the past year, he is continuing to devote forenoons to his work there. Dr. Heisler is a graduate of Temple University Medical College.

* * *

Dr. Stewart Thomson, associate professor of public health at the University of Minnesota, has taken the late Dr. W. A. O'Brien's place as radio commentator on health topics under the sponsorship of the Minnesota State Medical Association. Dr. Thomson's twice-a-week broadcasts, according to every indication, are receiving a very favorable reception from the laity.

* * *

Principal speaker at a meeting on March 9 of the Duluth Health Council, newly formed co-ordinating unit for twenty-four local agencies, was Dr. Donald A. Dukelow, director of the Health and Medical Care Division of the Minneapolis Council of Social Agencies. Dr. Dukelow was introduced to the group of public health workers from Duluth and neighboring communities by Dr. Mario Fischer, Duluth city health director.

* * *

The medical situation in Luverne was expected to be back to normal by March 1. For several weeks before that the entire medical burden had been carried by Dr. F. W. Bofenkamp and Dr. J. S. Burleigh. However, on February 22, Dr. O. W. Anderson returned from the

uth, and by the end of that week, Dr. C. L. Sherman as expected to arrive home from Rochester, where he d undergone an operation.

* * *

Stating that although there are still 100,000 new cases rheumatic fever annually, Dr. Thomas Hall, of the niversity of Minnesota pediatrics department, who oke at a pediatrics continuation course in early March, id that the nation's total "case load" of rheumatic fever ctims is diminishing each year. He gave as one of e principal reasons for the decrease, the increasing vareness of parents and physicians alike of the condi- ns which can lead to the disease.

* * *

Albany acquired a new physician early in February hen Dr. John J. Smyth began practice in the city as associate of Dr. F. H. Baumgartner. Dr. Smyth, a aduate of the University of Iowa College of Medicine 1944, served his internship at St. Mary's Hospital, uluth, after which he became a resident physician at opeming Sanatorium. He then served in the navy for ie and a half years and was discharged at the end 1947.

* * *

In a talk before the Jean Templeman Nurses Legion st in Saint Paul on March 4, Dr. Harold S. Diehl, an of medical sciences at the University of Minne- ta, discussed the heart research professorship to be onsored by the American Legion in Minnesota. Serv- es of the most able scientists in the country will be ught with professorship funds provided by the legion, he stated. The $500,000 endowment campaign, now being conducted by the state department of the American Legion, will end on May 23.

* * *

The St. Louis County Advisory Committee on Tuberculosis met in Virginia on March 1 to plan future operations of the county's mobile x-ray unit. Completion of a citywide x-ray survey in Duluth, scheduled for April, would finish the coverage of St. Louis County by mobile unit, a task begun in September, 1943. Meeting with the committee to determine future continuance of the chest examination plan were Dr. R. W. Backus, director of the mobile unit, and Dr. G. A. Hedberg, medical director of Nopeming Sanatorium.

* * *

Dr. E. G. Oppen, Minneapolis, has announced the association of Dr. S. G. Egge in the practice of medicine, with offices at 427 La Salle Building in Minneapolis. Dr. Egge, who was graduated from the University of Minnesota Medical School in 1943, interned in Seattle, Washington, then served in the army medical corps for two and one-half years. During his period of military duty he served as a neuropsychiatrist at the Hospital Center, Camp Carson, Colorado, and as a medical officer with the 86th Infantry Division in the Southwest Pacific.

* * *

Two busy days were spent in Salt Lake City in March by Dr. H. W. Walters of Rochester. On March 8 he presented a paper entitled "The Liver and Biliary Tract in Relation to Surgical Lesions" at a meeting of the

Salt Lake County Medical Society. On the morning of March 9 he spoke to medical students of the University of Utah on the subject, "Medical Education in Relation to Clinical and Experimental Studies of Disease." That evening, at a meeting of the Salt Lake Surgical Society, he presented a paper entitled "A Comparison of Vagotomy and Other Surgical Procedures in the Treatment of Peptic Ulcer."

* * *

Resignation of Dr. F. M. Feldman, Rochester, as city health officer was announced on February 21. Dr. Feldman resigned from the office, after serving for seven years, to accept a position with the United States Public Health Service as director of the central co-ordination and analysis office of the tuberculosis study section of the Division of Research Grants and Fellowships. In his resignation he stated that he had arranged to stay in Rochester until June 1, if necessary, in order that the changeover to his successor could be carried out with the least disruption of the city health program.

* * *

Social and health workers from four counties, meeting in Winona on February 19, heard Dr. David T. Carr, Rochester, urge that the old-fashioned social stigma against tuberculosis be transformed into a stigma against not treating it. Pointing out that tuberculosis is in the No. 1 spot in robbing the nation of useful man-years, Dr. Carr stated that public opinion should be against the person with tuberculosis who fails to submit to treatment. Dr. Carr's talk which was one of a series on the care and understanding of tuberculosis patients, was heard by social and health workers from Fillmore, Dodge, Olmsted and Winona counties.

* * *

Among physicians attending a five-day refresher course in pediatrics at the University of Minnesota during the first week of March were Dr. T. P. Groschupf, Bemidji; Dr. Henry Van Meier, Stillwater, and Dr. Charle M. Zeigler, Pine River.

Topics discussed at the course included infant feeding immunizations, pathology of cerebral palsy, the approac to the handicapped child, heart problems in childhoo and heart surgery, the Rh factor, and anemias of in fancy and childhood. Conducted by University of Min nesota staff members, the course was supported by th Minnesota Society for Crippled Children and Adults.

* * *

Discovery of another supplementary method for th diagnosis of cancer was announced early in March b Dr. George E. Moore, Minneapolis, who described th technique in the March issue of *Science*.

The method developed by Dr. Moore, who has a fel lowship in surgery at the University of Minnesota, i based upon the use of a Geiger counter and a radio active dye which is injected intravenously in patients The dye is retained by malignant tissue, and its pres ence is detected with the Geiger counter. Though no accurate in revealing most internal growths, the metho works almost perfectly in cancer of the central nervous system, Dr. Moore stated.

* * *

Approximately 800 physicians and surgeons from seven midwestern states and three Canadian provinces attended a two-day sectional meeting of the American College of Surgeons in Minneapolis on March 15 and 16.

Among Minnesota physicians who appeared on the program were Dr. Owen H. Wangensteen, Dr. L. Haynes Fowler, Dr. E. T. Bell, Dr. James M. Hayes, Dr. Stanley R. Maxeiner, and Dr. N. Logan Leven, all of the University of Minnesota, while Mayo Foundation faculty members from Rochester who spoke included Dr. John M. Waugh, Dr. Gordon B. New, Dr. Mark B. Coventry, Dr. Winchell M. Craig, and Dr. Fred Z. Havens.

* * *

In an article in the *Journal of the American Medical Association* early in February, an effective treatment for brucellosis was announced by four Minnesota physicians.

Dr. Wesley W. Spink, professor of medicine at the University of Minnesota, and his colleagues, Dr. James M. Shaffer, Dr. A. I. Braude, and Dr. Wendell H. Hall, reported the results of treating thirty-five cases of brucellosis, many with either streptomycin or sulfadiazine and nine with a combination of the two drugs. Of the nine patients treated with the sulfadiazine-streptomycin combination, all but one seemed to recover, and that one slowly improved after more intensive therapy. The drug combination appeared to be far more effective than any other treatment yet tried.

* * *

After practicing at Foley for the past year, Dr. Ralph . Mach has become associated in practice with Dr. oseph E. Halpin at Rush City. A graduate of the niversity of Minnesota Medical School, Dr. Mach egan his new duties on March 1.

* * *

General chairman of the 1948 fund drive by the Hen-epin County chapter of the Minnesota Cancer Society Russell D. Ekblad, Minneapolis branch manager of the un Life Assurance Company of Canada. The annual ampaign for funds began on April 1. President of the Hennepin chapter, which is conducting the drive, is Dr. ames A. Johnson, Minneapolis.

* * *

In International Falls on February 26 it was announced that Dr. C. C. Craig would be honored by ity and County Employes Local 510. The union planned dedicate the patient's room it was sponsoring at the alls Memorial Hospital to Dr. Craig in recognition of is years of service to his community.

A native Minnesotan, Dr. Craig was a woodsman in he border country from 1895 until 1910. He then ntered the University of Indiana School of Medicine, rom which he received his medical degree in 1917. mmediately after graduation he returned to Koochi-hing County and International Falls, where he has ontinued to practice medicine for thirty-one years.

* * *

Forty-three Rochester physicians spend part of their pare time singing.

Under the direction of Dr. Bruce E. Douglass, they onstitute the Mayo Foundation Fellows Chorus, a group f young physicians who like to get together after their ork is done for the evening and sing. Organized in 943 by Dr. Douglass and Dr. Donald C. Balfour, Jr., he chorus is primarily for the enjoyment and enter-ainment of its own members, but it has also given sev-ral programs in Rochester and has appeared in concert vith other musical groups.

Chief soloist in the group is Dr. U. L. Seferovich of Belgrade, Yugoslavia, a widely known singer in his ative land before he went to Rochester for further nedical education. Assistant director of the medico-ocal organization is Mrs. Douglass, who also serves he chorus as accompanist and chief critic.

* * *

Ten orthopedic clinics for crippled children will be eld in Minnesota before summer arrives.

The clinics, which began in St. Cloud on April 3, re made possible by state and Federal funds and are art of the health and welfare program of the Minne-ota Division of Social Welfare, under the direction f Dr. F. F. Callahan, chief of the Medical Services Unit. Sponsored by Crippled Children Services, the linics are open to those under twenty-one years of age, nd services include medical examination, diagnosis and

recommendation for treatment. Approximately 800 children were examined at the clinics held last fall.

Schedule for the spring clinics is as follows: St. Cloud, April 3; Austin, April 9; Faribault, April 10; Thief River Falls, April 17; Brainerd, April 24; Worthington, May 1; Detroit Lakes, May 8; Grand Rapids, May 15; Moose Lake, May 22; Morris, June 5.

Among groups co-operating in conducting the clinics are the Minnesota Public Health Association, Minnesota State Medical Association and local county medical societies.

LYON-LINCOLN COUNTY SOCIETY POSTGRADUATE EXTENSION COURSE

The thirty-seventh semi-annual postgraduate extension course of the Lyon-Lincoln County Medical Society began on April 20 in Marshall, Minnesota. The course consists of seven weekly dinner meetings followed by scientific programs, and will continue until June 1.

The scientific programs for the meetings, which were arranged by Dr. W. H. Valentine, Tracy, chairman of the program committee, are as follows:

April 20.—"The Role of the Antihistaminic Drugs in the Treatment of Allergy," by Dr. William S. Eisenstadt, Minneapolis.

"Some Metabolic and Endocrinologic Disturbances Which Masquerade as More Common Medical Conditions," by Dr. Edmund B. Flink, University of Minnesota Medical School.

April 27.—"Recent Advancements in Pediatrics," by Dr. James F. Bosma, Minneapolis General Hospital.

May 4.—"A Consideration of the Certain Variations in the Anginal Syndrome," by Dr. R. D. Pruitt, Mayo Clinic, Rochester.

May 11.—"The Pathology and Treatment of Glomerulonephritis," by Dr. Moses Barron, University of Minnesota Medical School.

May 18.—"Diverticula of the Gastrointestinal Tract" and "Recent Developments in Abdominal Surgery," by Dr. James A. Johnson, University of Minnesota Medical School.

May 26.—"Dermatology in General Practice," by Dr. Henry E. Mickelson, University of Minnesota Medical School.

June 1.—"A Fracture Conference on the Upper Extremities. Movies on Colles Fractures, and Discussion," by Dr. Earl L. Henrikson, University of Minnesota Medical School, and Dr. M. C. Nelson and Dr. Dan Moos, Minneapolis General Hospital.

BLUE SHIELD NEWS

Number of persons covered by Blue Shield as of March 15, 1948	12,687
Number of Blue Shield cases paid on March 15, 1948	56
Total for 1948	87
Amount paid on Blue Shield cases on March 15, 1948	$2,215.88
Total for 1948	$3,307.38

In attending various county medical society meetings we have been asked many questions that we feel should be answered and cleared up. It is only logical to assume that if these questions arise one place they will come up in another. As it would be practically impossible to contact each physician in the state and answer his questions individually, we are going to take advantage of the generosity of MINNESOTA MEDICINE in allowing Blue Shield space, and use it to answer the more important questions.

We have had many questions asking how the physician is to ascertain the patient's income, that is, whether it is more or less than $1,500 for the single person or more or less than $2,500 for the husband and wife or family. Those of us who have been asked this have given the answer, "What do you do now?" That, of course, requires a little more explanation.

First of all, we would like to explain the income limits. When Blue Shield was first considered, many such plans throughout the country were studied, that is, those with service contracts, those with indemnity contracts and those with service and indemnity contracts. It was finally decided by the House of Delegates that the Minnesota Medical Service, Inc., should offer a service and indemnity type of contract. The income figures under which service benefits would be allowed were arrived at by studying the figures and actuarial experience of other plans and also by the consensus as to what the limit should be in Minnesota. The limits were then set at $1,500 for the single person and $2,500 for the family. The $2,500 for the family includes the

alaries of all employed persons in the family who contribute to the support of the family. It also includes eal and other assets that a person may have, such as a farmer who has a large farm and derives most of his food, such as meat and vegetables, from it.

It may be interesting to note that in the various Blue Shield plans the income limits vary from $1,500 for a single subscriber to $5,000 for a family. The limits common to most plans are $2,000 for a single subscriber and $3,000 for a family. In Minnesota, about 20 per cent of the population is eligible to receive service benefits.

Now to get back to the question. The person's income status could be determined either by the corporation or by the attending physician. If the corporation were to determine the subscriber's income status, it was felt that it would be incorrect in many instances. For example, if at the time an applicant enrolled in Blue Shield he were asked to indicate whether he was a Limited subscriber or an Unlimited subscriber, he might truthfully state Unlimited but a year later, after changing jobs, he might become a Limited subscriber. Thus, if such a subscriber were treated by a participating doctor of medicine, the corporation would treat this subscriber as Unlimited which would be very unfair to the physician. Secondly, if the corporation were to determine the subscriber's status, such determining would tend to interfere with the patient-physician relations, which the contract definitely states it will not do. As a result, it was felt that since the physician is in direct contact with the patient, knows the patient's home life, his occupation and his status in the community, he (the doctor) was the most logical person and in the better position to determine the patient's income. Further, the physician is accustomed to doing this very thing in his present relationship with his patients.

In completing the form, consider the patient as you do now, and if you feel that his income and assets would place him in the Limited class, place him there. If the patient is one whom you would ordinarily charge a low fee, show him as Unlimited. In other plans throughout the country, this procedure has been carried out, and a very small percentage of the subscribers raise any question about being listed either as a Limited or as an Unlimited subscriber. In the event such a question should arise, contact the Blue Shield office and every effort will be made to help you.

HOSPITAL NEWS

In Le Sueur, at a meeting of the board of directors of the Commercial Club on February 9, a five-man committee was named to formulate a plan of action in regard to the hospital construction program proposed in Minnesota. Under the plan worked out by the Minnesota Department of Health, Le Sueur is in eighth place in the state for Federal funds to aid in building a suggested thirty-three-bed hospital. Named as chairman of the committee was Dr. S. Ericson.

plete hospitalization, medical and surgical services for up to seven days to students suffering injuries or acute illnesses during the school year. The new plan was announced on February 20.

* * *

A maternity home was opened in Blooming Prairie on February 13. Operated by Mrs. Mark Vanderbrook, the home has been equipped to meet the approval of local physicians and is being run under standard hospital rules.

* * *

At the annual election of officers of the Virginia Municipal Hospital on March 9, Dr. David A. Sher was elected president of the hospital to succeed Dr. C. B. Cunningham. Dr. Sher is associated with the Lenont-Peterson Clinic in Virginia.

Elected as vice president of the hospital was Dr. John S. Siegel, Virginia, while Dr. John Kochevar, Eveleth, was named secretary.

* * *

In Princeton, Dr. W. R. Blomberg was elected president of the Community Hospital medical staff at a meeting on March 11. He succeeds Dr. A. T. Kapsner in the position. Other officers elected at the meeting of the staff were Dr. Elton F. Clothier, Elk River, who was named vice president, and Dr. William F. McManus, who became secretary-treasurer, succeeding Dr. James T. Crabtree.

* * *

New head of the St. Cloud Veterans Administration Hospital is Dr. Claud Lewis, former manager of the Fort Meade (S. Dak.) Hospital, who began his new duties in St. Cloud on March 20. He succeeds Dr. John Pringle, former head of the hospital, who has retired.

A graduate of Washington University Medical School, St. Louis, Missouri, in 1924, Dr. Lewis began his career with the Veterans Administration in 1931 as a physician at Downey, Illinois. In 1935 he was transferred to the Waco, Texas, VA hospital, and in 1944 he was commissioned by the army medical corps, serving as a lieutenant colonel with the VA. While still an army officer, Dr. Lewis became manager of the Fort Meade Hospital in 1946.

* * *

A delegation of five Clearbrook businessmen spent March 11 inspecting the Littlefork Hospital and conferring with Dr. Ralph D. Hanover, Littlefork. Purpose of the delegation was to gather information and ideas to aid in the planning of a hospital which the Clearbrook community expects to build during the summer.

* * *

Plans for the Caledonia Community Hospital began taking shape on March 16 when a committee met and elected temporary officers of the newly formed hospital association.

Official name of the group will be the Caledonia Community Hospital Association, Inc. Tentative plans of the organization call for purchase of the existing but inadequate hospital building and development of a program of alterations and repairs to increase both capacity and efficiency of the hospital.

Named as members of the temporary board of trustees, serving only until the first organizational meeting of the association members, were Dr. Jacob J. Ahlfs and Dr. Neil T. Norris, both of Caledonia.

* * *

A mass meeting was held in Waverly on March 23 to point out benefits of a proposed new hospital for the area. Among speakers at the meeting, which was held to enlist support of residents of Waverly and the surrounding area, was Dr. C. L. Roholt of Waverly.

The proposed hospital, which will be partly financed by Federal funds, will be a thirty-two bed hospital and will cost $200,000. A fund-raising drive, conducted by a group headed by businessmen of Howard Lake, had gathered $44,500 in pledges by the middle of March, aiming at a $50,000 goal by May 1 and an eventual goal of $70,000.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

ATHOLOGY OF TUMORS. R. A. Willis, D.Sc., M.D., F.R.C.P. Sir William H. Collins, Professor of Human and Comparative Pathology, Royal College of Surgeons, London. Formerly Pathologist to Alfred Hospital; Consultant Pathologist to the Austin Hospital for Chronic Diseases, and Lecturer on the Pathology of Tumours in the University of Melbourne, Australia. 1521 pages. Illus. Price $20.00, cloth. Butterworth & Co., Ltd., London, England, and C. V. Mosby Co., St. Louis, 1948.

SYCHOBIOLOGY AND PSYCHIATRY. A Textbook of Normal and Abnormal Human Behavior. Second Edition. Wendell Muncie, M.D. Practicing Psychiatrist; Chairman Medical Advisory Board, Seton Institute, Baltimore, Md.; Associate Professor of Psychiatry, Johns Hopkins University; Consultant in Psychiatry, U.S.V.A. 620 pages. Illus. Price $9.00, cloth. St. Louis: C. V. Mosby Co., 1948.

EART. A Physiological and Clinical Study of Cardio-Vascular Diseases. Aldo A. Luisada, M.D. Instructor in Physiology and Pharmacology, Tufts College Medical School Lecturer in Medicine; Lecturer, Postgraduate Division, Tufts College Medical School; Associate in Medicine, Beth Israel Hospital, Boston, Mass.; former Professor of Medicine, Ferrara, Italy. 653 pages. Illus. Price, $10.00, cloth. Baltimore: Williams & Wilkins Co., 1948.

HYSIOLOGY OF EXERCISE. Laurence E. Morehouse, Ph.D., Associate Professor of Physical Education, University of Southern California, formerly Research Fellow, Harvard Fatigue Laboratory; and Augustus T. Miller, Jr., Ph.D., Associate Professor of Physiology, University of North Carolina Medical School. 353 pages. Illus. Price $4.75, cloth. St. Louis: C. V. Mosby Co., 1948.

HE BATTLE OF THE CONSCIENCE. A Psychiatric Study of the Inner Workings of the Conscience. Edmund Bergler, M.D. 296 pages. Price $3.75, cloth. Washington, D. C.: Washington Institute of Medicine, 1948.

NCYCLOPEDIA OF MEDICAL SOURCES. Emerson Crosby, Kelly, M.D., F.A.C.S., Associate Professor of Surgery, Albany Medical College; Attending Surgeon, Albany Hospital; Editor, Medical Classics. 476 pages. Price, $7.50, cloth. Baltimore: Williams & Wilkins Company, 1948.

PERATIVE GYNECOLOGY. H. S. Crossen, M.D., and R. J. Crossen, M.D. 6th edition. 1,000 pages. Illus. Price, $15.00. St. Louis: C. V. Mosby Co., 1948.

The sixth edition of Crossen and Crossen's Operative Gynecology, published in 1948, is not a larger volume than the fifth edition of 1938, but it contains a greater number of illustrations and more of these are in color. In order to hold the book to reasonable size and still incorporate new material, the authors have eliminated much that was interesting from the historical standpoint.

The discussion on prevention and cure of carcinoma of the pelvic organs has been enlarged. Preoperative and postoperative radiation are discussed and advocated.

Various methods for the correction of retro-displacement of the uterus are again described, but, in the discussion, the authors make the statement that most of the symptoms ascribed to retro-displacement are due to complicating conditions. This is in line with the modern trend of thought of most gynecologists.

Irradiation treatment, after curettage for myoma of the uterus, is discussed at greater length than previously. The authors have used this method in a selected series of patients. The pro's and con's of such therapy are discussed.

Throughout the book, most of the discussions include references to more detailed papers on the various subjects, so that the reader may investigate the subject further.

This is an excellent summary for those interested in operative gynecology.

SELMA C. MUELLER, M.D.

UNIPOLAR LEAD ELECTROCARDIOGRAPHY. Emanuel Goldberger, B.S., M.D. 182 pages. Illus. Price $4.00. Philadelphia: Lea & Febiger, 1947.

This is an excellent monograph and a convincing plea for more extensive study of the heart's electrical potentials by the clinical cardiologist.

Wilson, in 1942, before the Association of Life Insurance Medical Directors of America, sounded the keynote for unipolar leads. Since then several fairly extensive studies along the same line of approach have appeared. Some of us who have employed the limb leads for twenty-five years and adopted the exploratory electrode on the chest with the indifferent pole at a distance have felt fairly secure in our interpretations.

The finer methods suggested in Goldberger's book will have to be adopted in some instances by us in spite of the extra labor, time, and expense involved.

The monograph is highly recommended to the clinical cardiologist.

MODERN NURSING

SCHOOL OF PSYCHIATRIC NURSING

★

A one-year course is offered to girls over 17 years of age.

★

Small charge for matriculation, such as nurses uniforms, cape and other necessary incidentals.

★

June class now being formed

Glenwood Hills Hospitals is currently offering to qualified applicants a one year course in psychiatric nursing. The course was originally laid out by a group of University of Minnesota professors and hospital staff members, and is the product of careful thought on their part. The curriculum has been streamlined to fit the modern needs of the modern methods of patient treatment. The subject matter has been consolidated and reduced to factual information directly applicable to the nurses work. The time necessary for completion was a foremost consideration. Only through an intensified course of this type can the training be accomplished in a short time and the student quickly released to a position of productivity within the profession.

The increased demand for nurses due to expanding hospitalization plans and the steady loss of trained nurses to marriage has resulted in an endangering shortage. This situation can only be rectified through your help and an accelerated program of training.

FREE ILLUSTRATED BOOKLET

As a Doctor, you can materially assist in overcoming this shortage by enumerating the advantages of a nursing career to young ladies in your community. Glenwood Hills Nursing School has prepared an illustrated booklet describing in word and pictures the facilities available to the student nurse.

May we suggest that you fill in the card below with the name of a girl in your community who would be a potential candidate for the June class. Do this as your contribution in aiding the national drive to recruit more nurses.

This baby's mother learned about Mead's Oleum Percomorphum from her physician, not from public advertising or displays.
"Servamus Fidem"
HOW much sun does the infant really get?
Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Mead's Oleum Percomorphum is a prophylactic against rickets available 365¼ days in the year, in measurable potency and in controllable dosage. Use the sun, too.
Mead Johnson & Co., Evansville, Ind., U.S.A.

THEELIN is a *naturally occurring* estrogen. It is well tolerated and can be administered without significant side reactions or untoward effects.

THEELIN is a *pure crystalline* estrogen. Since it is not a mixture and does not contain extraneous substances, its physiologic effectiveness is accurately determined by weight.

eadership in estrogen therapy

THEELIN is a *highly potent* estrogen. One ten-thousandth (0.0001) of a milligram is equivalent to one international unit. Because of THEELIN's potency, symptoms of the menopause and other estrogen-deficiency states may be readily and effectively relieved.

THEELIN is a *dependable* estrogen. It has stood the test of time. The first estrogenic hormone to be isolated in pure crystalline form and the first to assume clinical importance, THEELIN may be depended on for its reliable and predictable estrogenic effects.

THEELIN is available as **THEELIN AQUEOUS SUSPENSION** in ampoules of 1 mg. (10,000 I.U.), 2 mg. (20,000 I.U.) and 5 mg. (50,000 I.U.);
THEELIN IN OIL in ampoules of 0.1 mg. (1000 I.U.), 0.2 mg. (2000 I.U.), 0.5 mg. (5000 I.U.) and 1 mg. (10,000 I.U.);
STERI-VIAL® THEELIN IN OIL in vials of 10 cc., each cc. containing 1 mg. (10,000 I.U.); and
THEELIN Vaginal Suppositories, containing 0.2 mg. (2000 I.U.).

middle age + pleasurable living

Perhaps, at no other time does a woman need reassurance so much as during the trying period of the menopause when physical and emotional instability threaten her feeling of security.

Equanimity of spirit and body may often be restored with **"Premarin."** *This naturally occurring, orally active estrogen offers many advantages but undoubtedly one of the most gratifying effects of therapy is the "sense of well-being" usually expressed by the patient...the "plus" in* **"Premarin"** *which gives the woman in the climacterium a new lease on pleasurable living.*

To adapt estrogen treatment to the individual needs of the patient three **"Premarin"** *dosage forms are available: tablets of 2.5 mg., 1.25 mg. and 0.625 mg.; also liquid 0.625 mg. in each 4 cc. (1 teaspoonful).*

While sodium estrone sulfate is the principal estrogen in **"Premarin,"** *other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water soluble conjugates.*

"PREMARIN"®

CONJUGATED ESTROGENS (equine)

HOLLAND-RANTOS COMPANY, INC., 145 HUDSON STREET, NEW YORK 13, N.Y.

Merle L. Youngs PRESIDENT

"the substance from which they obtain the greatest comfort"...

"Some patients are relieved of hot flushes by synthetic drugs, but fail to obtain quite the sense of well-being they experience when given natural estrogens; there is no reason to deny these patients the substance from which they obtain the greatest comfort."[1]

AMNIOTIN, Squibb complex of natural mixed estrogens, does *more* than relieve climacteric flushes and sweating. The patient not only experiences a feeling of well-being, but increased strength and vigor and "a greater sense of general relief, exclusive of the amelioration of hot flashes."[2] These advantages, long attributed to natural estrogens, are attained with Amniotin therapy.

Amniotin is well tolerated. It is readily metabolized by the body, and detoxified by the liver. Moreover, the natural estrogens in therapeutic doses are less likely to induce menopausal bleeding or hyperplasia of the endometrium.[3]

Whether symptoms are mild, moderate or severe, oral and intramuscular forms of Amniotin in a variety of potencies fulfill every need. Capsule suppositories are also available.

DO YOU KNOW WHAT THESE SYMBOLS STAND FOR?

Rexall

DRUGS

YOU CAN DEPEND ON ANY DRUG PRODUCT THAT BEARS THE NAME REXALL.

Samuel Plimsoll fought bitterly against the overloading of merchant ships which caused disasters at sea. From his fight came this symbol. It sets a limit beyond which a ship may not be burdened. To the seaman, this "Plimsoll mark" is a symbol of safety through rigid control.

Another symbol of safety through rigid control is the blue and white symbol of Rexall. About 10,000 conveniently located, independent drug stores display the familiar Rexall sign. It is your assurance of reliable pharmaceuticals and superior pharmacal skill in their compounding.

S-M-A® builds husky babies

Protein in S-M-A is complete and adequate. It is present in the same proportion as in breast milk. Protein in S-M-A is *utilized for growth.*

Because the fat and carbohydrate in S-M-A are perfectly balanced (as in human milk) to supply necessary energy, the protein element in the formula is available for its own special purpose—the building of tissue. Thus growth factors are not robbed to supply caloric requirements.

S-M-A closely approximates mother's milk.

The S-M-A formula is well suited to modification, as the physician may wish, for special feeding problems.

THIS SUGGESTION MAY BE OF VALUE FOR YOUR THROAT PATIENTS:

When cigarette smoking is a factor in throat irritation, many leading nose and throat specialists suggest* to their patients a choice of 3 alternatives:

1. Stop Smoking,

2. Smoke less,

3. *Change to* Philip Morris!

• Philip Morris is the *only* cigarette proved definitely and measurably less irritating!** Perhaps you too will find it worth while to suggest "*Change to* PHILIP MORRIS."... by far the wisest choice for *everyone* who smokes.

PHILIP MORRIS

Philip Morris & Co., Ltd., Inc.
119 Fifth Avenue, N. Y.

DO YOU SMOKE A PIPE? We suggest an unusually fine blend — COUNTRY DOCTOR PIPE MIXTURE. Made by the same process as used in the manufacture of Philip Morris Cigarettes.

**Completely documented evidence on file.*
***May we send you copies of these published studies:*

Laryngoscope, Feb. 1935, Vol. XLV, No. 2, 149-154; Laryngoscope, Jan. 1937, Vol. XLVII, No. 1, 58-60; Proc. Soc. Exp. Biol. and Med., 1934, 32-241; N. Y. State Journ. Med., Vol. 35, 6-1-25, No. 11, 590-592.

HOW MANY LIKE HIM ARE YOUR PATIENTS?

FOR EACH OF THEM 7,500 HOGS ARE NEEDED

It takes one ounce of crystalline insulin to provide 40 units per day for 40 years. To make one ounce of insulin, the pancreatic glands from 7,500 hogs or 1,500 cattle are needed. Insulin and other glandular medicinals are available to your patients only because the meat packers of America save the pancreatic and other glands for pharmaceutical purposes. Without an adequate livestock population, serious and even life threatening shortages of these drugs would develop.

ORAL ESTROGEN

ESTINYL®

(ethinyl estradiol)

"specially active . . . giving extraordinarily good results by oral administration . . ."[1]

Unrivaled potency permits *minute* dosage—*measured in hundredths of a milligram*—for rapid alleviation of menopausal distress and other estrogen-deficient states. Rarity of side reactions is noteworthy in therapeutic dosage. Promotion of a gratifying sense of well-being is a conspicuous feature of ESTINYL therapy. Low cost permits the prescription of ESTINYL* to any office patient for potent, highly effective, well-tolerated, oral estrogen therapy.

DOSAGE:
One ESTINYL Tablet of 0.02 mg. daily. Severe cases two to three tablets a day or 0.05 mg. as required; the dosage being reduced as symptoms subside.

ESTINYL (ethinyl estradiol) Tablets of 0.02 mg. (buff) or 0.05 mg. (pink), in bottles of 100, 250 and 1000. ESTINYL LIQUID, 0.03 mg. per 4 cc., in bottles of 4 and 16 oz.

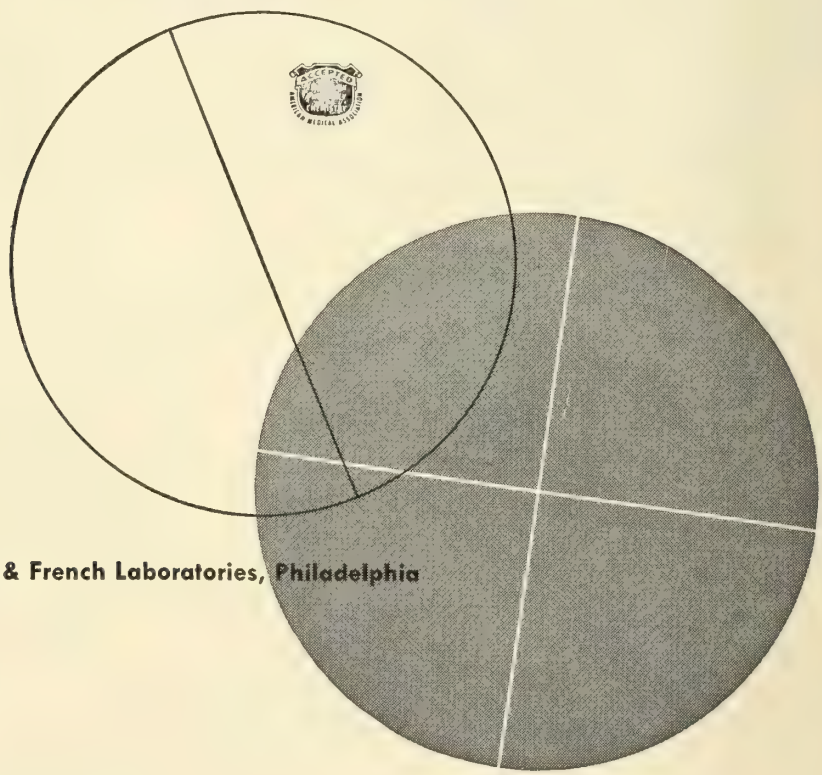
to help vanquish depression marked by "morning tiredness"



Many depressions are marked by morning tiredness, inertia, lassitude and retardation. 'Benzedrine' Sulfate, taken on awakening, frequently helps to lift the patient "over the hump" of the early hours.

Benzedrine Sulfate—where it shortens, eases, or even eliminates the patient's struggle with depression—may improve the tone of his entire day. While not always effective, Benzedrine Sulfate therapy certainly merits a fair clinical trial in depression marked by morning tiredness.

When life is measured in days

Not years, nor months, but days measure the life of a new-born infant. And during the first 30 days when infant mortality is at its highest, every effort must be made to minimize the hazards to life. At this critical time, the right start on the right feeding can be of vital importance.

'Dexin' has proved an excellent "first carbohydrate." Because of its high dextrin content, it (1) resists fermentation by the usual intestinal organisms; (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds.

Readily prepared in hot or cold milk, 'Dexin' brand High Dextrin Carbohydrate is palatable but not too sweet. 'Dexin' *does* make a difference.

From the day that powerful, short-acting Pentothal Sodium was first introduced by Abbott in 1934, the index of reports on its use for intravenous anesthesia has grown rapidly. Coming from every corner of the globe, from every land in which modern surgery is practiced, the file of literature on Pentothal Sodium now lists more than 1070 reports, 90 of which were published last year. This worldwide record—impressive tribute to an anesthetic developed by a single commercial laboratory—covers every phase of the use of Pentothal Sodium: indications and contraindications, advantages and disadvantages, techniques of administration and precautions to be observed. With such a guide, Pentothal Sodium can be employed for intravenous anesthesia safely, effectively and conveniently. Interested in more information about this product? Just drop a line to Abbott Laboratories, North Chicago, Illinois.

Experience is the Best Teacher

Camillo Golgi (1844-1926)

proved it in neurology

Golgi is best remembered today for his detailed investigations of the finer microscopic structures of the nervous system. Golgi's improved methods for staining nerve cells and fibres, as well as his own histologic experiences, assisted in the development of the clinical study of neurology.

R. J. Reynolds Tobacco Company
Winston-Salem, N. C.

Experience is the best teacher in cigarettes, too!

With millions of smokers who have tried and compared different brands of cigarettes, Camels are the "choice of experience." Try Camels! See how your taste welcomes the rich flavor of Camel's choice, properly aged, expertly blended tobaccos. See if your throat doesn't find Camel's cool mildness mighty pleasing.

Yes! Let your own experience tell you why more people are smoking Camels than ever before.

According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

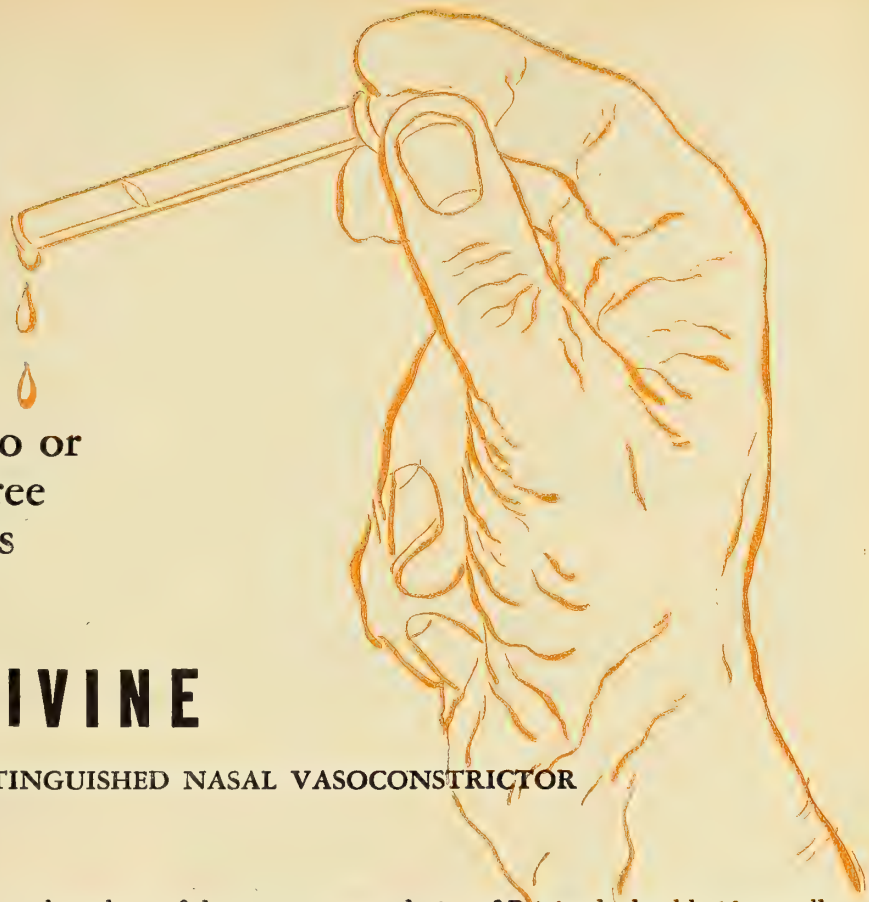
Three leading independent research organizations in a nationwide survey asked 113,597 doctors what cigarette they smoked. The brand named most was Camel!

Borden's prescription specialties are flexibly adaptable to cope effectively with the sharply increased number of your infant feeding problems.

BIOLAC—a complete infant formula (only vitamin C supplementation needed) for infants deprived of mother's milk.

DRYCO—a powdered, high-protein, low-fat, moderate carbohydrate milk food ideally suited for all formulas.

BETA-LACTOSE—an exceptionally palatable, highly soluble milk sugar for formula modification.



MULL-SOY—a hypo-allergenic emulsified soy food for infants and adults allergic to milk proteins. The 1:1 standard dilution approximates cow's milk in fat, protein, carbohydrate and mineral content.

KLIM—a spray-dried whole milk with soft curd properties essential in infant feeding and special diets. Particularly valuable when availability or safety of fresh milk is uncertain.

only two or three drops

PRIVINE

A DISTINGUISHED NASAL VASOCONSTRICTOR

high potency Only two or three drops of the 0.05 per cent solution of Privine hydrochloride usually give prompt and complete relief of nasal congestion and hypersecretion.

prolonged action The effect of each application of Privine provides two to six hours of nasal comfort, thus avoiding the inconvenience of frequent re-application.

bland and non-irritating Privine is prepared in an isotonic aqueous solution buffered to a pH of 6.2 to 6.3. Artificial differences in osmotic pressure between solution and epithelium are avoided; stinging and burning are usually absent.

relatively free from systemic effects Although a sedative effect is occasionally noted in infants and young children — usually after gross overdosage — Privine is generally free of systemic effect. The absence of central nervous stimulation permits the use of Privine before retiring without interfering with restful sleep.

• CIBA PHARMACEUTICAL PRODUCTS, INC., SUMMIT, NEW JERSEY

Excellence

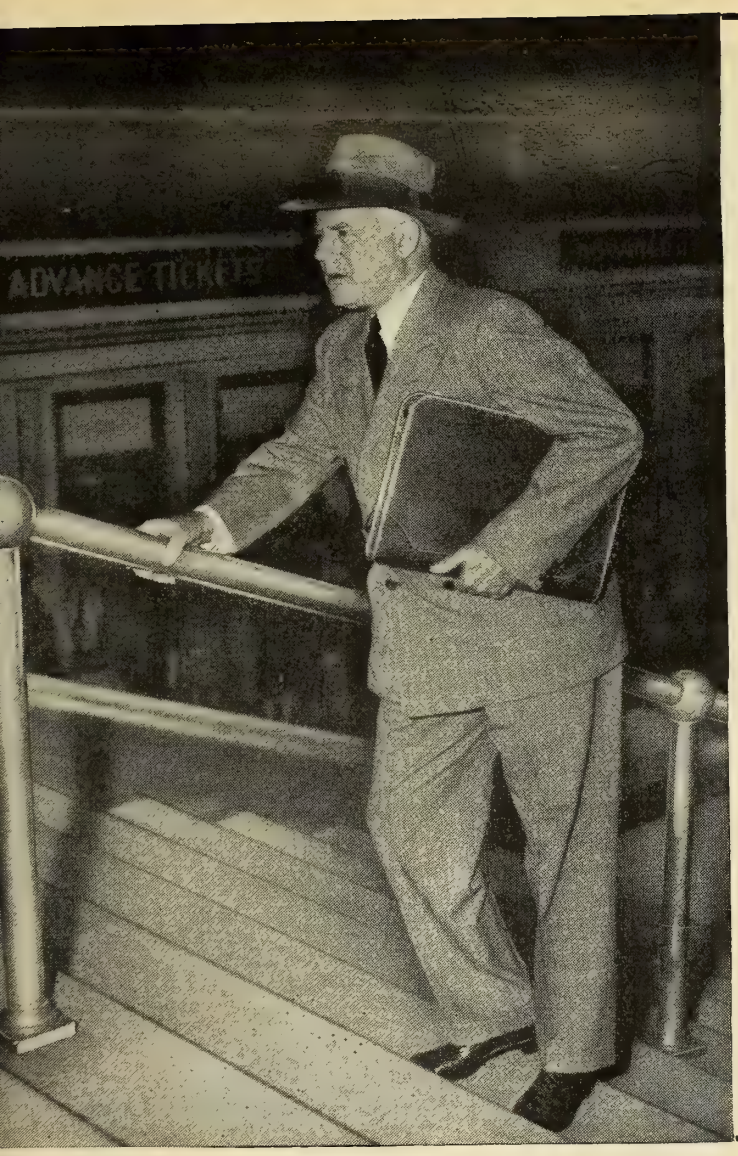
...is a fact

...not a compromise

THE BECK-LEE MODEL E ELECTROCARDIOGRAPH

Of primary consideration is the *accuracy* of the electrocardiograph . . . *excellence* with which there is no compromise.

The Beck-Lee Model E *provides* TRUE recording of the heart current. Here is a sealed dust-proof, quartz string instrument incorporating TRUE photo-electric timing and TRUE meter measured millivolt standardization.



Having but two panel controls for obtaining quickly all seven standard limb and precordial leads, the Model E also features a daylight loading camera with autographing door, lead marker and footage meter. The operator seated comfortably in front of the instrument looks directly into the viewing screen while taking the cardiogram.

Complete with all necessary accessories and carrying case the Model E is moderately priced at $645.00. The matching mobile stand is $35.00.

MINNEAPOLIS MINNESOTA

ANGINA PECTORIS

and other Manifestations of

CORONARY INSUFFICIENCY

The following episodes may be prevented by appropriately regulated administration of a vasodilator having a *sustained* effect:

FOR THE PERSON

- ***who is compelled to stop and rest when climbing a flight of stairs.***
- ***who suffers "indigestion" and "gas" on exertion, or after a heavy meal.***
- ***who is stricken with precordial pain on unusual exertion or emotion, or when exposed to cold.***

The vasodilatation produced by Erythrol Tetranitrate Merck begins 15 to 20 minutes after administration, and lasts from 3 to 4 hours.

It is generally agreed that the acute attack of anginal pain is most readily relieved by the prompt removal of the provocative factor, and by the use of nitrites. For prophylactic purposes—to control anticipated paroxysms—the delayed but prolonged action *of erythrol tetranitrate is effective. Erythrol tetranitrate, because of its slower* and more prolonged *action, is also considered preferable for the purpose of preventing nocturnal attacks.*

MERCK MERCK MERCK

The First Pathology

Both Medicine and Dentistry thank Giovanni Morgagni of Padua (1682-1771) for studying the body's *abnormalities*, as Vesalius of Padua had studied its *normal* structure 200 years before. Morgagni watched *bodily changes due to disease*, as Sydenham had watched *symptoms*—and found, not Descartes' "misplaced soul juices," but changes "as natural as water running downhill." Pneumonia? Then the lungs would be "liver-red," not "fresh as a garland of fruit" (the symbol of health).

Morgagni had no microscope. But the Prussian Rudolf Virchow (1821-1902) *did*. So he found that, in diseased flesh, it was really the *cells* which were changed or disordered.

With Morgagni's pathology, John Hunter (1728-1793) made surgery a science of surgeons rather than meatcutters—but he couldn't aid the defense of a doctor accused of poisoning a British lord with cherry laurel water in 1781.

Doctors Since 1899 (three years before Virchow died) have been more fortunate. In the Medical Protective policy they have found *complete* protection, *preventive* counsel and *confidential* service—backed by the world's largest legal staff of malpractice specialists.

The advice is always "SEE YOUR DOCTOR"

To an audience of over 23 million people, in LIFE and other national magazines, Parke, Davis & Co. presents the message shown below. This is the 211th advertisement in the campaign in behalf of the medical profession, published continuously since 1928.

A reproduction in full color will be sent on request. Write Parke, Davis & Company, Detroit 32, Mich.

Some things you should know about reducing your weight

No. 211 in a series of messages from Parke, Davis & Co. on the importance of prompt and proper medical care.

It is an accepted medical fact that excess weight can impair your health and efficiency, and possibly shorten your life.

One person's proper weight may be quite different from another's however—even though their height and age are approximately the same. A large-boned, muscular person, for instance, should weigh considerably more than a small-boned person of the same height and age.

How much you should weigh is something to leave up to your doctor. Only your doctor can accurately judge whether your weight is within normal limits, or whether a loss or gain in weight is medically advisable.

If your doctor tells you that you weigh more than you should, it's just good sense to do something about it under his supervision. To undertake a weight-reducing program without proper medical guidance is a foolish, and often dangerous, thing to do.

It would be pleasant if there were some simple pill which would automatically and safely reduce your weight with no effort on your part. Unfortunately, *no such remedy exists.* So-called "reducing pills," taken without a physician's advice, are usually valueless and may be dangerous.

One type of pill, for instance, will cause you to lose weight—but only for a day or two! Its action is to remove water from body tissues, thus lowering your weight. But as soon as the water is replaced, the extra pounds are back again.

Another thing to beware of, in an effort to lose weight, is any sort of faddist diet.

A liquid diet may often be just as fattening as a normal one. A diet which concentrates on a particular food, and excludes most other foods, may deprive you of nutritive elements essential to the maintenance of good health.

See Your Doctor. Let him decide whether you should lose weight, how much you should lose, and how quickly. Let him tell you how you can do it without starving yourself, without risking your health. He can recommend a well-balanced diet. He can advise you about exercise. If he thinks medication will be helpful in your case, follow his instructions about dosage *exactly.* His advice is the only advice you can trust in matters that concern your health.

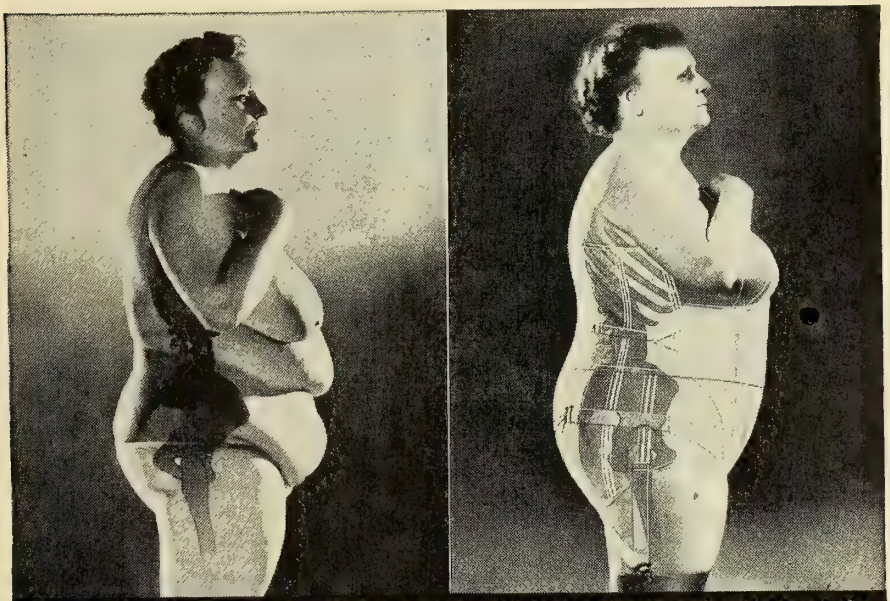
TRADE MARK



ANATOMICAL SUPPORTS

for

PENDULOUS ABDOMEN

The adjustment of the Camp Support lays a foundation about the major portion of the pelvic girdle. From this foundation, the upright sections of the support hold the load up and back and give excellent support to the lumbar and lower dorsal regions.

The holding of the load furnishes not only relief to the spine but also lessens the drag of the viscera upon the diaphragm.

Photographs—Obese patient with 3rd degree pendulous abdomen and arthritis of the spine before and after application of abdominal and breast supports. (Skeletons indrawn.)

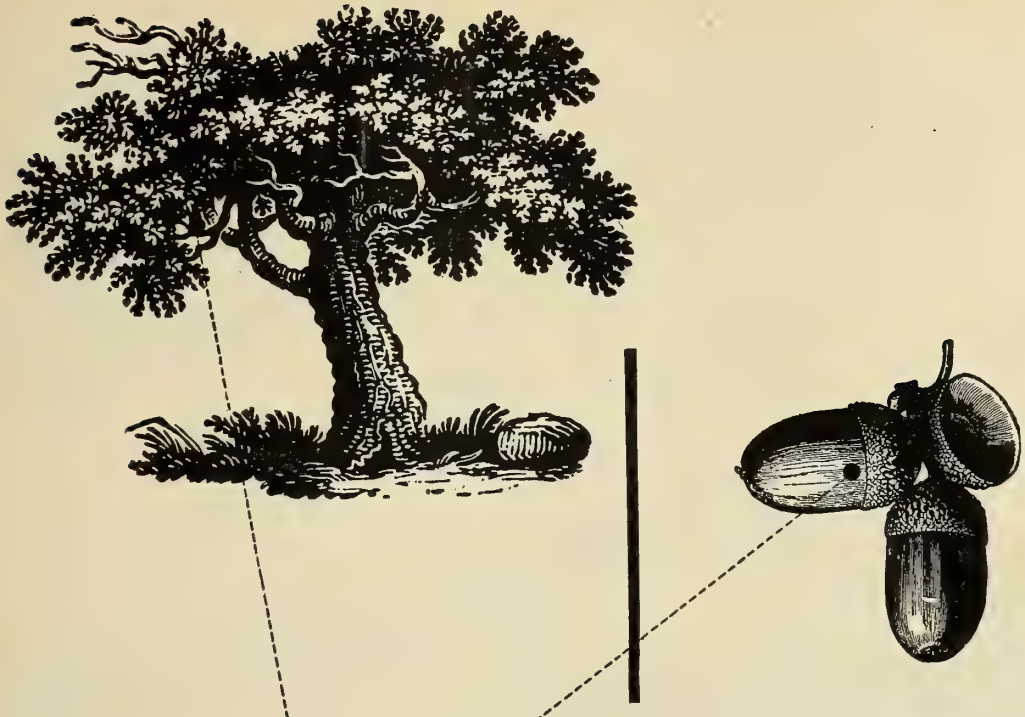
A POOR POINT OF VIEW!

. . . With so much going on in the world it's a shame to emulate the traditional position of the ostrich . . .



. . . Busy physicians, with heavy working schedules, often are tempted to "get away from it all" by laying aside their professional journals and relaxing with the latest "who dunit" murder mystery . . .

. . . Relaxation is fine, but too much is happening in the world of medical science and medical economics to remain out of professional circulation for more than a short time . . .

. . . MINNESOTA MEDICINE gives you the latest information on scientific matters, news of the profession, and also what is new in drugs, medical appliances, and special services. Don't overlook the educational value of the ads. You can trust their reliability, for only products accepted by A. M. A. councils are advertised . . . Most offer samples.* Write for them and in that way help us prove the point we often make, that . . . "Minnesota physicians read their state medical journal."

THE DRUG ADDICT

E. M. HAMMES, M.D.

Saint Paul, Minnesota

DRUG addiction in its broadest sense applies to any individual who either for physical or psychological reasons has developed a compelling need for certain drugs.

A physician's wife, a bed-ridden invalid because of her many psychosomatic symptoms, was rehabilitated after prolonged hospitalization to the extent that she again attended to her home duties and became an asset to her community. That was eight years ago. However, she still needs and demands her 5-grain placebo capsule for sleep. Without it, she develops her own abstinence symptoms of fear, apprehension, nervousness and insomnia. Psychologically she is a drug addict to the same degree as the alcoholic who has to drown his sorrows or the morphine addict who requires his hypodermic to meet his personality difficulties.

Habit-forming drugs may be classified into two categories: the narcotic group, and the various types of sedatives and hypnotics. Since many recent articles in the literature have emphasized the dangers and accumulative effects of the bromides, this drug is gradually losing its popularity. However, the various hypnotics are amply replacing them with greater detriment to the patient in many instances. So many physicians still find it less time-consuming to give patients some sedative for their many psychosomatic complaints than to devote a little energy to the finding of a brief explanation of their functional symptoms and their significance. With psychosomatic medicine forging to the foreground, and with more thorough scientific training in this field, the medical profession is becoming more conscious of this important phase of daily practice.

According to Federal statutes, the narcotic drugs are opium and its derivatives, cocaine, marihuana, heroin and demerol, and addiction to these substances is legally narcotic drug addiction. For many years pharmaceutical laboratories have attempted to develop a pain-relieving non-habit-forming drug as a substitute for morphine. Both pantopon and demerol were so considered when first introduced to the medical profession. Unfortunately, the number of narcotic addicts due to pantopon and demerol is rapidly increasing. Recently, a similar drug, methadon (6 dimethylamine-4-4-diphenyl-heptanone-3), has been developed as an effective analgesic. In a recent article published by the United States Public Health Service,[4] it states that "it is the unanimous opinion of all who have been concerned with the evaluation of the addiction liability that methadon like morphine is dangerous with respect to habituation." Another new analgesic drug, AN-148, recently introduced, was given to 106 patients for relief of pain without any evidence of addiction.[1] However, in a more recent case of brachial plexus tumor, a definite dependency to this drug developed.[8]

Himmelsbach[3] stated that addiction to the opiate drugs embraces three related phenomena: (1) tolerance or the gradual decrease in the effect produced by the repeated administration of a drug; (2) physical dependence, which is manifested by the appearance of a characteristic illness if the drug is withheld, and (3) habituation or psychic dependence, which implies an intense desire for

From the Department of Psychiatry and Neurology, University of Minnesota Medical School.

the repetition of pleasurable effects associated with the use of a drug.

In the non-narcotic group are alcohol, paraldehyde, the various barbiturates, especially veronal, amphetamine or benzedrine, rarely ether by inhalation, and similar drugs. These differ in the main from the narcotic group in that they do not produce a physical dependence and their rapid withdrawal is accompanied by very slight abstinence symptoms.

Monroe and Drell[7] made a special study of the prison population at the U. S. Disciplinary Barracks, Fort Benjamin Harrison, Indiana, to determine the number of benzedrine addicts. Two hundred and sixty-four inmates (24.4 per cent) indicated they had used benzedrine, either in pill form or by chewing the strips from benzedrine inhalers. One hundred and thirty had taken it prior to enlistment in the army or prior to confinement. In a room of one of the guards, over 300 empty inhalers were found which had been sold to the inmates for from 75 cents to $1.50 per tube. The three main reasons for taking the drug were: it made the time go faster, it made them feel happier, and it made them talkative. Withdrawing the drug precipitated weakness, depression, gastrointestinal disturbances and tremor. Four of the inmates developed ideas of reference and hallucinations.

During the past year we had one patient who took a large amount of benzedrine and thyroid (dose undetermined) for a period of five weeks and developed an acute maniacal state and died from exhaustion. A postmortem examination revealed a marked hemorrhagic pulmonary edema. A second patient, who averaged 150 mg. of benzedrine daily for at least four months, developed delusions of infidelity about his wife and periods of viciousness and uncontrollable temper.

According to Hambourger,[2] more than 1,200,000,000 grains of barbiturates were sold in the United States in 1936. U. S. Census Bureau figures show that there were 171 suicides and 165 so-called accidental deaths due to the barbiturates during that same year. These cases are cited to illustrate the extensive use of some of these drugs, frequently considered harmless, and to point out their detrimental effects. The pernicious habit, quite prevalent among students, of taking benzedrine in the morning to keep alert for lectures and examinations, and of taking barbiturates at night to produce sleep, may cause serious consequences and should be definitely discouraged.

Certain types of individuals are more prone to become addicts than are others. Stille[11] has well stated that those who have a propensity to employ some artificial means of promoting the flow of agreeable thoughts, of emboldening the spirit to perform acts of daring, or of steeping in forgetfulness the sense of sorrow, are more likely to embrace narcotics and fall a victim of their enslaving effects than are those who do not possess these propensities.

In 1938, Kolb and Ossenfort[6] classified addicts into six main groups. In 1925, Kolb[5] had suggested a somewhat similar grouping based on a personality study of 230 addicts which included life history, heredity, personality defects, emotional reactions, intelligence and other characteristics.

Kolb's classification consisted of the following major categories:

1. Normal individuals, accidentally addicted because of illness.
2. Psychopathic diathesis.
3. Psychoneurosis.
4. Psychopathic personality without psychosis.
5. Inebriates in whom excessive alcoholic indulgence acts as a precipitating factor in the addiction.
6. Drug addiction associated with a frank psychosis, either organic or functional.

On the basis of this classification, Pescor[9] made a study of 1,036 patients admitted to the United States Public Service Hospital in Lexington, Kentucky, during the fiscal year July 1, 1936, to June 30, 1937.

He found that only 3.8 per cent came under Group 1, normal individuals accidentally addicted.

Group 2, the psychopathic diathesis, comprised the largest number (54.5 per cent). Their most frequent reason for addiction was curiosity and association with addicts.

Group 3, those with psychoneurosis, comprised 6.3 per cent. Therapeutic necessity caused by somatic complaints were the main excuse for their addiction.

Group 4, the psychopathic personalities, comprised 11.7 per cent, and their main reason was curiosity and association.

The fifth, or inebriate, group comprised 21.9 per cent, and the typical inebriate individual resorted to the drug as a means of sobering up after

alcoholic sprees. This psychopathic impulse which develops his craving for alcohol also compels him to take narcotics.

In the sixth group, there was only one patient suffering from senility, who took the drug to "set his mind at rest."

In a general way, there are two types of drug addicts: (1) the emotionally stable individual who acquires the addiction accidentally, and whose normal personality make-up will be re-established, after he recovers from his physical illness and is relieved from his drug addiction; and (2) the psychopathic individual who becomes an addict through curiosity or association, or as a sequence to his inadequate personality. The prognosis as to relapses and the method of treatment are radically different in these two groups.

Drug addiction is a universal problem. In order to determine its extent in Ramsey County, I reviewed the Ancker Hospital records. The total number admitted to Ancker Hospital from 1932 to 1947 (15 years) was 265. A few of these were nonresidents and some were admitted more than once. One hundred eighty-three were addicted to morphine, twenty to heroin, six to dilaudid, and thirteen were cocaine addicts. Six were habituates to paraldehyde and forty-seven to the various barbiturates. In only two per cent was the addiction acquired because of illness. To this number should be added the various drug addicts admitted to the private hospitals in Ramsey County. This information was not available. As most of the Ancker Hospital patients obtained their narcotic drugs from peddlers, each patient was thoroughly questioned as to the source of supply. In only one instance was this obtained. Evidently these patients were fearful that if any information were given their supply would be discontinued after their discharge from the hospital. One of our most interesting cases was a man of sixty-one, who was given a prescription for laudanum (Tr. Opii) for abdominal pain at the age of twenty. For forty-one years he took laudanum, up to 6 ounces daily, until the Harrison Narcotic Act was passed. He then entered Ancker Hospital voluntarily. With a gradual reduction treatment, he made a satisfactory recovery and remained well.

During the past fifteen years, we hospitalized and treated in our private practice forty-two drug addicts and had an opportunity to review the records of fifty-seven others—a total of ninety-nine narcotic addicts. Among this group were business and professional men, college graduates and farmers; eighty-eight were men, and eleven women. These differed in the main from the Ancker Hospital group in that because of favorable financial circumstances they could more readily obtain their narcotic drugs from prescriptions or similar sources. Nine of our women patients had received their first narcotic prescription or hypodermic from the family physician because of migraine headaches, severe menstrual pains, sciatica, duodenal ulcer and similar disorders. One of our demerol addicts, who developed the addiction while attending her sister who required demerol because of a malignancy, had been given, during previous two years, pantopon at least twice monthly for migraine headaches. Among the group of eighty-eight male patients the youngest was twenty-seven years old, the oldest eighty-one, and the average was forty-eight years. Morphine was used by every patient at some time during the period of addiction. In addition, eighteen resorted to dilaudid at irregular intervals, ten to demerol, five to cocaine, six to pantopon, two to heroin and six to codeine. The largest dose in two cases was 12 grains of morphine daily; twenty-six used alcohol to excess, and twenty-nine required hypnotics regularly. Eleven wives of these eighty-eight patients developed the narcotic habit instigated by their husbands. Only one of these wives was hospitalized under our supervision with her husband. Like the social drinker, many addicts love companionship.

The most oustanding difference between this group and any other group that has been studied is the fact that fifty-one (over 50 per cent) gave some physical cause for their addication, compared to 3.8 per cent or even less in other groups. Perhaps because of their better education and more secure environment, they rationalized and obtained some moral comfort in an attempt to justify their addiction. This attempt to utilize minor ailments as an etiologic factor is itself suggestive evidence of their psychopathic personality. Headache, rheumatism, arthritis, hernia, hay fever, asthma, frequent colds and hemorrhoids were some of the causative illnesses stated. Severe attacks of kidney stone, intestinal hemorrhages, lightning pains of tabes and malignancy were among the serious diseases given, and were perhaps justifiable reasons to develop a narcotic ad-

diction. Only twenty-nine (about 33 per cent) gave some emotional causative factor, such as nervousness, home and financial worries, overwork and experimental desire. In the remaining nineteen cases, no reasons were given by the patient for the addiction. When we consider all these etiologic factors in addition to the twenty-six who were alcoholic and the twenty-nine who required hypnotics, it would appear that, regardless of education or environment, the psychopathic personality types have the greatest tendency to develop drug addiction.

Observations of this comparatively small group of private patients conform to the statistical study by Pescor[10] of 100 male and 100 female patients admitted to the U. S. Public Health Service Hospital, Lexington, Kentucky. He found that the male addicts began the use of narcotics through association and curiosity (and I might add for minor ailments), and were inclined to use more than one kind of narcotic drugs. The female group became addicted for the relief of some painful or distressing physical condition and generally confined itself to the use of morphine.

According to Federal regulations, physicians are not permitted to dispense narcotics for patients except for definite diseases discovered during the examination of the patient. This excludes the indiscriminate writing of prescriptions to drug addicts drifting into physicians' offices. During the past year, a narcotic addict touring Minnesota was given seven dilaudid prescriptions for various amounts by seven different physicians during a period of two weeks. The trail of this individual was investigated by the Federal Narcotic Agents, to the embarrassment of several of these physicians.

The treatment of a drug addict cannot and should not be attempted unless he is willing to be hospitalized under proper regime and control, either voluntarily or through an order from the Probate Court. The period of hospitalization should be at least three months. It has been our custom to use the gradual reduction method. It is associated with less physical discomfort and pain, complications are very infrequent, and the patient is more co-operative and more willing to continue with the program, an important factor with patients voluntarily hospitalized. Frequently these patients are irritable, demanding and unreasonable. They are often undernourished and require high caloric diets and vitamins to improve their physical condition. Tonic doses of insulin are beneficial. Sedatives should be given as necessary to alleviate the many functional complaints and symptoms. We have found it very satisfactory to give sedatives in plain capsules, which enables one to lessen the dose gradually without altering the size of the capsule. Frequently, these patients are familiar with all the known sedatives and hypnotics, and recognize them by the color of the capsule.

The most important phase of the treatment is to re-educate the individual, to increase his ability to endure discomfort, to teach him to exercise more self-control, to correct his habit of taking some medication whenever he is unhappy or uncomfortable, to assist him in the readjustment of some of his social and economic problems and in his rehabilitation. The danger and tendency to a relapse should be fully explained to him, for the "cock-sure" attitude is always a serious and uncertain one. After discharge from the hospital these patients further require careful supervision and reassurance for several months at least, to assist them in maintaining their proper morale and co-operation.

At the best, when treating psychopathic personalities, the future is always uncertain, and only with prolonged and encouraging guidance can one anticipate permanent results.

Through the efforts of the late Herman Johnson, for many years chairman of the Public Policy Committee of the Minnesota State Medical Association, in conjunction with the excellent supervision of the Minnesota State Board of Medical Examiners and its attorney, Manley Brist, Minnesota holds a unique position for the care of its physicians who are unfortunate enough to become drug addicts. It is difficult to understand why any physician should become addicted to narcotics, being fully aware of the dangers of and the distressing effects from such an addiction, besides the risk of being deprived of his medical license. The fact that the drug is so easily accessible, the mistaken belief that an occasional hypodermic to relieve fatigue or mental distress is harmless, and the egotistical attitude that one can deceive the Federal narcotic agents, are probably the main reasons for the initiation of the narcotic addiction.

Any physician licensed in the State of Minnesota and detected as a narcotic addict by the Fed-

THE MORE COMMON METHODS OF INGUINAL HERNIA REPAIR

A Comparison of the Recurrence Rates

DAVID SANDERSON, M.D., and CARL O. RICE, M.D.
Minneapolis, Minnesota

IN the preparation of this article, the different techniques, suture materials and anatomic structures used in hernia repair, as described in a large series of reports, have been studied in order to compare them and to determine, if possible, the most suitable method of repair. Several other aspects of hernia will be discussed, such as the time of recurrence, type of recurrence, recurrences in the young and aged, and also the procedure used by one of us in St. Barnabas Hospital, Minneapolis.

Techniques

The most common method of repair of inguinal hernia has been the Bassini technique, introduced in 1890, in which the internal oblique and transversus abdominis muscles are sutured to Poupart's ligament under the cord. The sac is ligated high. There have been many other methods used since then. They differ from the Bassini operation in the placement of the cord and in the use of different anatomic structures for closing the defect. The more common variations are the Halsted I, placing the cord subcutaneously; the Halsted II and Ferguson, with the cord deep to the internal oblique; the E. Wyllys Andrews, with imbrication of the external oblique around the cord; Bloodgood's rectus muscle or flap closure; Edmund Andrews' tucking of the transversalis fascia; McArthur and Gallie fascial strips; Wangensteen's pedicle flap, and the McVay Cooper's liagment repair. By a comparative study we have hoped to determine what method should be used in the repair of inguinal hernia. Only reports in which most of the cases were followed by physical examination are included. A follow-up by letter is not reliable, as shown by Taylor, and by our experience.

Bassini

Bassini's operation consists primarily of high ligation of the sac and suturing of the internal oblique and transversus abdominis muscles to Poupart's ligament under the cord (Fig. 1). Results from this technique are indicated in Table I.

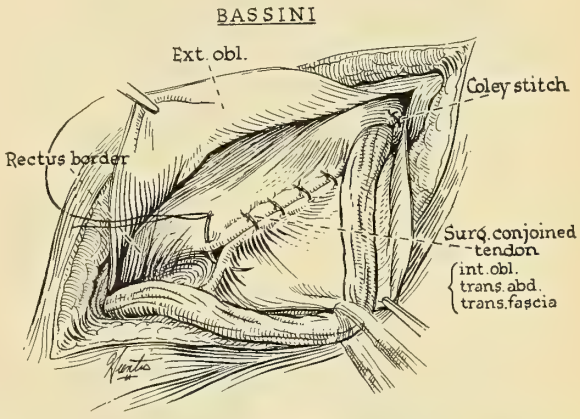

Fig. 1. Bassini operation. The floor of the canal is closed with interrupted stitches by suturing the surgical conjoined tendon to Poupart's ligament.

Recurrent Hernia				
Shelley (1940)	59	12	20.0	

Halsted I

In Halsted's first operation the cord was transplanted subcutaneously above the external oblique aponeurosis. The internal oblique muscle was incised transversely for a short distance at the internal ring and the cord moved into the incision. The edge of the internal oblique was then sutured to Poupart's ligament under the cord. The eternal oblique then was imbricated under the cord, thus eliminating the external ring completely (Fig. 2). At first, Halsted excised the larger veins of the cord. However, later he discontinued this pro-

	112	20	Av.: 17.8	

Ferguson Operation

Ferguson's operation is essentially the same as Halsted's except that he omits the suturing of the cremasteric fascia under the internal oblique and the imbrication of the external oblique (Fig. 4).

Bloodgood

Bloodgood made an incision along the lower border of the rectus muscle and brought the rectus, the internal oblique and transversus abdominis

muscles down to Poupart's ligament (Fig. 5). In 1903, Bloodgood and Halsted introduced a rectus flap repair for direct hernia. The recurrence rate with the first procedure is too high to warrant its use, as indicated in Table IV.

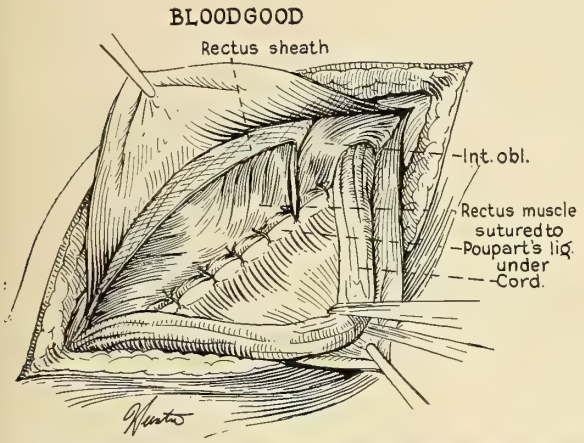

Fig. 5. Bloodgood operation. The rectus muscle and sheath are sutured to Poupart's ligament under the cord.

Estes (1941)	72	2	2.77	

Mattson-Bloodgood-McVay

Dr. Hamlin Mattson of Minneapolis, while in the service with the armed forces in 1943, devised a technique for hernia repair which he recommends when the transversalis fascia and conjoined tendon prove inadequate for repair. He swung a rectus and pyramidalis flap down to Cooper's ligament to fill in the floor of Hesselbach's triangle (Fig. 6). He repaired 24 difficult direct and recurrent hernias by this method. It may eventually prove that this procedure will combine the favorable end results of each of these.

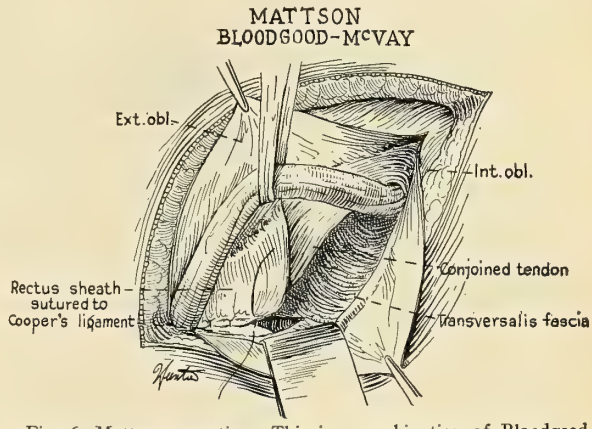

Fig. 6. Mattson operation. This is a combination of Bloodgood and McVay procedures in which the rectus fascia is sutured to Poupart's ligament under the cord. It essentially blocks an approach to the floor of the canal.

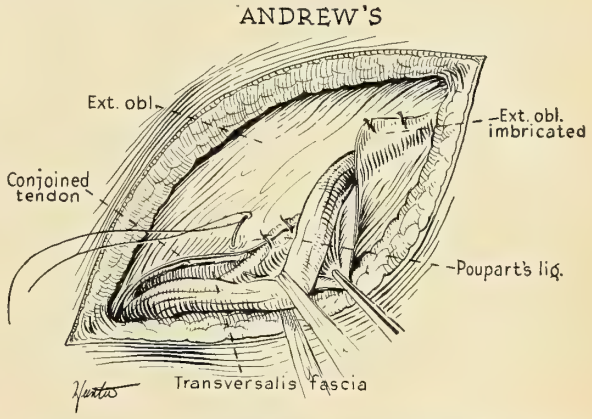

Fig. 7. Andrews operation. The external oblique fascia and conjoined tendon are sutured to Poupart's ligament under the cord. The cord is placed between the imbricated outer leaf of the fascia of the external oblique.

E. Wyllys Andrews

Andrews brought the upper flap of the external oblique aponeurosis and the internal oblique muscle together down to Poupart's ligament. He placed the cord upon these structures and swung the lower flap of the external oblique over the cord, leaving the cord between the imbricated flaps (Fig 7).

TABLE VI. RECURRENCE RATE—E. WYLLYS ANDREWS

Joyce reported very good results with the Andrews imbrication using the McArthur fascial strip as suture material.

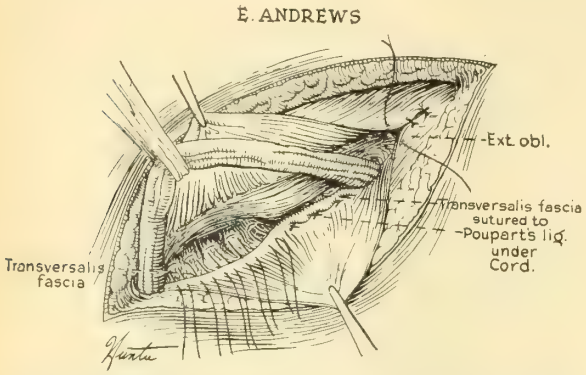

Fig. 8. Edmund Andrews operation. This consists of a tucking of the transversalis fascia and suturing it to Poupart's ligament under the cord.

Edmund Andrews

In 1924, Edmund Andrews stressed the utilization of only "white fascia" in the repair of hernia. He separated the transversalis fascia from the internal oblique muscle and sutured a pleat of fascia alone to the shelving portion of Poupart's ligament (Fig. 8). He also imbricated the external oblique. Only one reliable follow-up study with this type of repair has been found in the literature (Table VII).

TABLE VII. RECURRENCE RATE—EDMUND ANDREWS

Burton & Ramos (1940)	457	34	7.5	3 yrs.
	Recurrent Inguinal Hernia			
Burton & Ramos (1940)	64	9	14.0	

Wangensteen

Wangensteen has used a pedicle flap of the iliotibial tract by swinging the latter over the inguinal ligament and filling the defect with fascia lata. Burton has modified the technique by bringing the flap through the femoral canal. This procedure is usually reserved for the more difficult hernias in which there is a large defect to be repaired.

TABLE VIII. RECURRENCE RATE—WANGENSTEEN

	No.	Recurrence	Per Cent Recurrence	Follow-up
Burton & Ramos (1940)	8	1	12.6	
Wangensteen (1934)	14	1	7.3	
Garner (1947)	6	0	0	1 yr.-10 yrs.
	28	2	Av.: 7.3	

McVay

McVay has popularized the use of Cooper's ligament as the anchoring point instead of Poupart's ligament in the repair of inguinal hernia (Fig. 9). Cooper's ligament had been used by Lotheissen in 1898, Babcock in 1927, Dickson in 1936, and others, but chiefly for femoral hernia repair alone. McVay uses a Rienhoff relaxing incision routinely in his repair. The available reports dealing with the end results from McVay's operation are very favorable (Table IX). Since the conventional procedures up to date have been only reasonably satisfactory, his technique deserves further trial and evaluation in the hope that greater assurance can be promised in the repair of hernia.

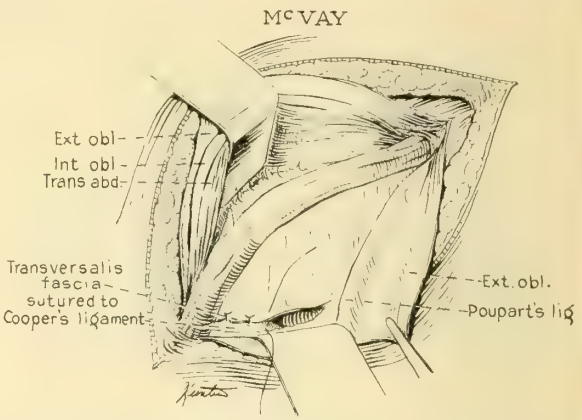

Fig. 9. McVay operation. The transversalis fascia is sutured to Cooper's ligament, thus blocking an approach to the floor of the canal.

McArthur and Gallie Fascial Strips

McArthur introduced the use of attached fascial strips from the external oblique aponeurosis as far back as 1901. However, the technique has not been widely used until the last ten to fifteen years. In 1921, Gallie found, after a thorough investigation with laboratory animals, that fascial grafts would remain viable if sutured

without tension. On the basis of that work, he used strips of fascia lata to repair inguinal hernia. One would assume that the McArthur fascial strip is more suitable than the Gallie strip, because the former is more readily available, and possibly more viable, since it is left attached. After comparing the recurrence rates of the two methods, we found the Gallie to be more satisfactory than the McArthur (Tables X and XI). However, it is a small series and no final conclusions can be made.

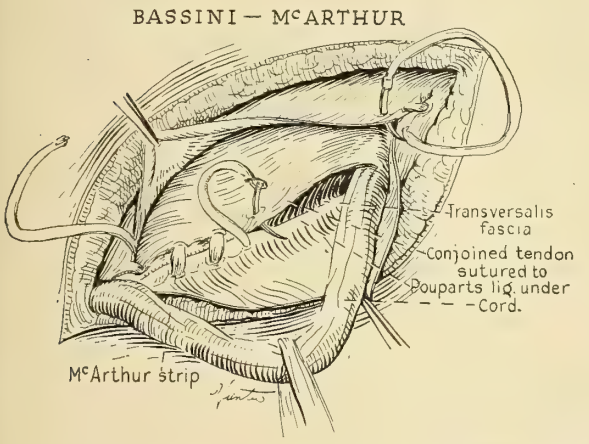

Fig. 10. Bassini-McArthur operation. McArthur recommended the use of locally available fascial strips and suggested that these could be used with any of the types of procedures. This illustration shows a Bassini type of closure in which the conjoined tendon is sutured to Poupart's ligament under the cord. The remaining strips merely close the fascia of the external oblique over the cord.

McArthur-Bassini-McVay

At St. Barnabas Hospital, we have been using a three-strip Bassini-McArthur (Fig. 10) or McArthur-Bassini-McVay procedure. The three strips are made from the upper flap of the external oblique; two are left attached at the pubic spine and one at the muscle end of the external oblique. The first strip is used to bring the internal oblique muscle snugly around the cord at the internal ring and to the inguinal ligament (Fig. 10). The remaining two strips close thereby re-establishing the inguinal canal. The end of the fascial strips are secured with fine wire. The advantage of this technique is that it eliminates all foreign suture material except a very small amount of wire, which produces little tissue reaction. Recently, we have modified this operation by suturing the transversalis fascia alone to Cooper's ligament without including the internal oblique and transversus abdominis muscle in this portion of the stitch (Fig. 11). We think that this operation provides double protection against protrusion of a hernia through the floor of the canal: first, by blocking the approach to the floor of the canal as the transversalis fascia is sutured to Cooper's ligament, and second, by reinforcing the floor of the canal as the edge of the conjoined tendon (internal oblique and transversus muscles) is approximated to Poupart's ligament.

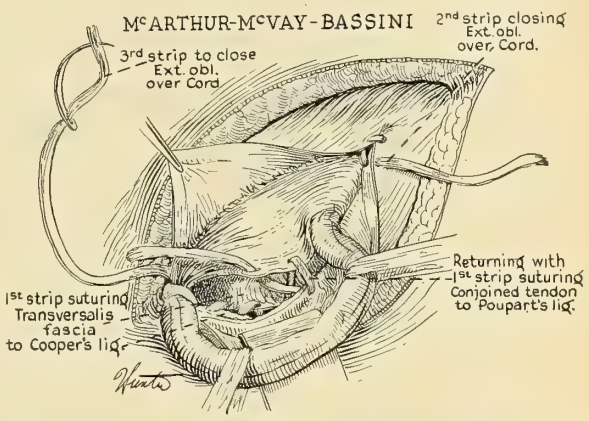

Fig. 11. McArthur-McVay-Bassini operation. Following the first strip, it will be observed that the transversalis fascia is sutured to Cooper's ligament, thus blocking the approach to the floor of the canal. The first strip continues back, approximating the conjoined tendon to Poupart's ligament, thus reinforcing the floor of the canal. The second and third strips are used merely to close the fascia of the external oblique over the cord, re-establishing the normal anatomical relationship of cord and inguinal canal.

An attempt was made to follow the hernia cases

in which this repair was used. One hundred and thirty-seven letters were sent out and there were 86 replies. We were able to examine only a small number of the patients. Several of the patients who stated they had a recurrence were mistaken, and one can safely assume that there were recurrences among the group who reported a good result. We therefore did not determine any recurrence rate, feeling that a follow-up by letter would not be sufficiently accurate.

Comparison of Chromic Catgut and Silk

Most surgeons agree that silk, cotton, and linen are more suitable than chromic catgut in hernia repair. There are skeptics, however, who argue that the suture material used does not effect the recurrence rates. Table XII should remove any doubt as to the value of nonabsorbable over the absorbable suture.

Comparison of Silk and Fascia

Some authors compare fascia to nonfascia, but the latter includes both chromic catgut and silk which should not be included together, as shown above. A more significant comparison would be between nonabsorbable suture and fascia, particularly to decide if fascia should replace nonabsorbable suture material in the simple hernia. The results in Tables XIII and XIV show almost identical recurrence rates.

Type of Recurrence

A large majority of recurrent indirect and direct hernias operated upon are found to be direct, a small number indirect, and very few femoral. One might argue that since so few hernias recur as femoral hernias, it should not be necessary to use a McVay procedure. However, on the basis of the figures in Table XIII and

XIV, it appears that the use of Cooper's ligament gives a smaller recurrence rate than was obtained by using the inguinal ligament.

When hernia recurs, most of them return as direct hernias as indicated in the following tabulations:

Burton and Ramos (1940)

130 Recurrences

Trilocular	1
Femoral	0
Others	21

Shelley (1940)

	Recurrence	
	Indirect	Direct
95 Indirect Hernias	10	85
115 Direct Hernias	8	107

Recurrence Rates Among Operators

Interns and residents have higher recurrence rates than the staff. Proceeding from the more experienced to the less experienced, they vary from none to 24.1 per cent (Taylor) and 0.8, 3.9 and 6.7 per cent (Joyce). Therefore, only the cases of the experienced surgeons should be used in a report if a new technique is to be evaluated accurately.

Method of Follow-up

Taylor showed the importance of following cases by personal examination rather than by letter from the patient or another physician (Table XVI).

TABLE XVI.

	INDIRECT			DIRECT		
	No.	Recurrence	Per Cent Recurrence	No.	Recurrence	Per Cent Recurrence
Patients examined at Johns Hopkins	356	30	8.4	47	14	29.7
Patients checked by letter	460	16	3.4	47	3	6.3
	816	46	Av. 5.6	94	17	Av.: 18.08

Hernia in the Young and Aged

Coley repaired 4,807 hernias in children, with only nineteen recurrences, or a 0.39 per cent recurrence rate. Frequently, the only repair necessary is simple high ligation of the sac or a Ferguson operation. Grace, Dubin, and Murray on the other hand report over a 20 per cent recurrence rate for the aged. Shelley showed that the recurrence rates of indirect hernia increase with age as follows:

0-20 yrs.	1.3%
20-40 yrs.	6.9%
40-60 yrs.	9.2%
60-80 yrs.	20.0%

The transversalis fascia is often thinned and weakened in elderly patients.

Time of Recurrence

The time of recurrence varies in the literature. Probably a majority of recurrences are within the first two years, but if an operator's recurrence ratio is to be accurate, his course should be followed at least three years, preferably five (Table XV).

TABLE XV.

	Less 6 mo.	Less 1 yr.	Less 2 yrs.	Over 2 yrs.	Over 3 yrs.
Burdich (1937)			60.0%	40.0%	
Judd (1908)	70.0%	90.0%			
Erdman (1923)		73.9%	98.6%		
Longacre (1939)		72.0%	87.2%		
Shelley (1940)			66.6%		25.0%

The studies made at St. Barnabas Hospital reveal that letters from the patient were not reliable. Many studies gleaned from the medical literature were not included in this paper because the cases were followed by letter or over too short a period of time. Those followed by letter have very low recurrence rates: some less than 1 per cent in large series.

Conclusion

1. The Bassini and the Halsted II operations have about the same recurrence rates, 5 to 6 per cent in indirect, and 15 to 18 per cent in direct hernias. These operations reinforce the floor of the inguinal canal.

2. The Halsted I and Bloodgood (rectus muscle) operations have such a high recurrence rate as to make these operations undesirable. The rectus fascia flap repair, however, gives good results.

3. Wangensteen's pedicle flap is an excellent repair for more difficult hernias.

4. Cooper's ligament repair gives lower recurrence rates in primary inguinal hernia than other procedures. This operation blocks an approach to the floor of the inguinal canal.

5. Silk, linen or cotton are definitely better suture materials than chromic catgut in hernia repair.

6. Silk and fascia, when used as suture ma-

terial, give about the same recurrence rates in primary inguinal hernia repair.

7. Most hernias recur as direct hernias through the floor of the inguinal canal.

8. A barrier against an approach to the floor of the canal (McVay), in addition to a reinforcement of the floor of the canal (Bassini), held permanently with suture material (McArthur fascial strip) appears to offer, on the basis of statistical analysis, advantages from each of these fundamental principles which have been evolved for the cure of hernia (Fig. 11).

9. Recurrence rates increase with age.

10. If recurrence rates are to be accurate, cases should be followed at least three years, preferably five.

11. Follow-up by letter is inaccurate.

LABORATORY FINDS RARE DISEASE

Two cases of sporotrichosis, a fungous disease very rare in Minnesota, were reported recently by the Medical Laboratories of the Minnesota Department of Health. Only one case had previously been reported to the Health Department as far back as 1932.

The disease is a chronic infection characterized by the development in the lymph nodes, skin, or subcutaneous tissues of nodular lesions which break down to form indolent ulcers. Evidence suggests that the infection is acquired from contact with plants, but it may also come from contact with infected animals. The fungus usually finds entry through the skin. The first lesion may appear from 20 days to three months after inoculation. The first evidence of the infection is the appearance of a hard, spherical, non-tender nodule. As the disease progresses, subcutaneous nodules appear along the lymphatics draining the area.

One of the recent cases in Minnesota, occurring in a St. Louis County man, apparently came from pricking his finger on a thorn while planting rose bushes last fall. This case was identified by the laboratory of St. Luke's Hospital, Duluth, and the identification corroborated by the Health Department. The other case, that of a woman in Brown County, started with an ulcer just above the elbow, and had no history of previous injury.

Fortunately, treatment with potassium iodide is practically a specific in the treatment of sporotrichosis, if given in adequate, rapidly increasing doses—*Minnesota's Health,* April, 1948.

HEMOSTASIS IN TONSILLECTOMY

G. M. A. FORTIER, M.D.

Little Falls, Minnesota

THIS article is written not in the belief that I am offering anything new in the technical field, but rather with the idea in mind that medical literature dwells neither long enough nor exactly enough on the important detail of hemostasis in tonsillectomy, thereby failing to impart much needed information to the general practitioner. The article is written also, therefore, in the hope that it will curtail the years of experience in general practice necessary to obtain the knowledge which a single article could have properly presented.

My desire is not to discuss the technique of tonsillectomies, except to note a few facts pertinent to the later development of my ideas on the treatment of postoperative hemorrhage. I believe that in shaving or snipping the tonsil capsule from its bed, care should be exercised to hug the tonsil, and also that a greater tension should be put on the tonsil with only a reasonable and much less pressure on the dissecting knife. Furthermore, the closer the lower pole is approached before snaring, the less hemorrhage may be expected, if the dissection is deftly performed. In most cases, it should be possible to shave out the tonsil completely, snaring merely mucous membrane.

Whatever technique is used, I feel that descriptive emphasis is wrongly placed on the procedure of enucleation, rather than on hemostasis. This latter, if we are to judge by the bulk of literature, is treated too lightly and as a secondary matter. Instead of meticulous ligation of bleeders, dependency is placed on pressure, use of icebags, pillar suturing, application of silver nitrate, Monsell's solution, thrombin, serum, novocaine and adrenalin injection at the point of bleeding, et cetera. All of these seemingly ignore the fact that in any other surgical procedure, in attempting to affect hemostasis, recourse is had only to ligation with no thought of employing doubtfully effective methods such as those above mentioned.

Field

The exposed surface following tonsillectomy presents itself as an anterior and posterior wall, meeting at a central perpendicular line. This is true only insofar as the area is left unmolested. Active tension on either the anterior or, especially, the posterior pillar, produces a flat surface, the trough being reduced.

The inferior "angle," from which has been removed the lower pole of the tonsil, appears as a well-like cavity. In this case, too, traction upward on either or both pillars near their inferior extremities elevates and obliterates the cavity. This may be accomplished, also, by grasping the bed (without clamping) in the vicinity of the lower pole raw area and exerting traction.

The area which previous to enucleation contained the superior pole of the tonsil is an actual cavity. It is usually more difficult to produce a clearly visible area at that point. However, here too, full vision of the entire surface may be obtained by traction distalward with concomitant upward traction by a pillar retractor on the hood of the cavity.

Thus, with good light, there should be reasonable assurance of full visualization of every recess of the exposed tonsillar bed.

Vessels

Either venous or arterial bleeding or both may issue from the upper pole area.

In the central area, unless the operation has been quite roughly done, the bleeding usually is only from a punctured or torn central vein, coursing vertically. Rarely is there a plexus of veins. In all cases the blood may be seen issuing from the particular point of injury to the vein.

As the lower pole is approached, on the inferior central surface, and usually on the "anterior" wall, there is present quite commonly an arterial hemorrhage, occasionally productive of a freely spurting issue.

The lower pole area may be the site of either arterial or venous bleeding or both. It is especially noticeable here, however, that bleeding is seldom brisk and soon ceases spontaneously. It is quite important to bear this in mind, as rapid filling of this area will frequently prove, when it is reduced by tension, to be the result of gravitation of blood from a superior area—this regardless of a low head positon.

There is no bleeder, in my experience, which cannot be fully visualized, if care is used.

In a tonsillectomy done under general anesthesia, if a bleeder is found in a particular location

Fig. 1. The La Force "Y" tier with rounded notch.

in one tonsil bed, a bleeder can be expected to be present in the corresponding location in the opposite tonsil bed. This anticipation is a valuable time-saver in seeking for bleeding points.

The "fire hose" type of bleeder is hardly as frightful or profuse a condition as the name seems to imply. Rather, it is a bleeder whose actions resemble those of an uncontrolled fire hose—a waving, curling action. The result is that, following sponging and ascertaining the position of the bleeder, a forceps applied at that point fails to cause hemostasis; or before clamping is attempted, it is realized the bleeder is no longer at that point. If the mechanics of the difficulty is not realized by the surgeon, he will eventually begin to clamp indiscriminately, grasping large areas of tissue and doing real harm. Good light and care will result in visualization of the vessel, which may be clamped above the elusive bleeding point. Pinhole or tear hemorrhages of veins are clamped at the bleeding point, with no more than the vein being caught in the grasp.

I have never encountered a general oozing. I feel that those in a state of hemorrhagic diathesis should be left unoperated upon. I believe that most of the "bleeding" cases are excuses for unskillful surgery or lack of meticulous care in ligation, the operator depending, rather, on ineffective, ill-chosen or antiquated methods because he considers the location and ligation of bleeding points an extraordinary procedure.

Instruments

For many years I have used satisfactorily a Wolf mouth gag with a self-retained tongue depressor. This mouth gag or any other of comparable design produces a field easily illuminated and completely envisioned.

Rochester-Pean's curved forceps are advisable, smaller forceps being impractical and difficult to manipulate.

The La Force "Y" tier, as illustrated in Figure 1, has been used by me for many years with complete satisfaction. It can be purchased from any of the surgical houses. It is important to note that the guide slots converge to a sharp angle. This angle should be rounded with a rat-tail metal file, so that during tension the instrument will exert no grip on the suture material, but rather will afford a smooth surface. Silk or cotton sutures are difficult to use; 00 catgut works well. In my experience, any type of trick tying forceps is cumbersome and impractical.

Following the original sponge pressure, small sponges, one-fourth the usual size, are used in seeking bleeders.

Technique

On several occasions I have practiced grasping bleeders as they became evident during enucleation. However, during the dissection there is free hemorrhage from the tonsil just as from the bed, resulting, in my experience, in difficulty in identifying bleeding points, thereby prolonging the operation. Furthermore, it is obvious that at this stage of the procedure, no effort can be made to tie without encountering many difficulties. The result of this technique, therefore, is that upon completion of enucleation of the tonsil, there will be many unnecessary hemostats in the field, most of them, incidentally, grasping excessive tissue.

It is most important that a grasp inclusive of any excess tissue be avoided. Not only is this destructive to muscle tissue, but also could be a direct cause of delayed hemorrhage due to slough.

Grasping excess tissue results in difficulty or failure to ligate securely. Furthermore, it is absolutely unnecessary, no matter how profuse the bleeding from a particular point. The intention of the operator should be to grasp and ligate only the involved vessel.

As the large sponge is slowly removed from the upper pole area, each bleeding point is clamped. This is at times awkward. Therefore, if proper suction facilities are to be had, the large sponge may be removed, and the operator

may resort to seeking with the smaller sponges and suction tip.

The pillar retractor is probably more valuable in depressing the posterior than in elevating the anterior pillar. If this is difficult, an intestinal Allys forceps may be used in drawing down the posterior pillar. Seemingly inaccessible areas are easily brought into view by grasping with the Pean forceps an adjacent area and drawing the bleeding field into view. If this is forgotten, what should be an easily remedied situation results in a seemingly hopeless problem.

Fig. 2. The knot approaches the point of the forceps. The forceps is rotated to face the approaching knot. The method of forcing the knot with one hand is unworkable.

If several hemorrhaging points are present, sponge pressure may be used to control them while each is tied. However, this is an extreme condition. I have never found it necessary to ligate more than five bleeders on a side. Usually they number two, rarely three. In all cases, the "terrific" bleeding from a tonsil bed, on careful inspection, manifests its origin as a single bleeding point.

Never have I found any suturing necessary. That should be properly relegated to the realm of bygone surgery. Except in inexcusable operations or in cases of hemorrhagic diathesis, the suturing of pillar over gauze is little less than an expression of ignorance of the principles of hemostasis. (I am referring to any hemorrhage within the eighteen-hour postoperative period.)

Ligating is comparatively simple but is subject to little difficulties which, if unsuspected, result in insecure ties. The difficulties, as illustrated, are:

1. Failure to slip the loop over the tip of the forceps. This is overcome by having the tip facing the approaching knot (Fig. 2).

2. One arm of the tier may be on the leader while the other is within the loop, resulting, surely, in a loose tie (Fig. 3).

3. Complete rotation of the forceps may be necessary to bring the tip in view out from under the hood or anterior pillar.

Fig. 3. Cause of a loose tie—one arm on the leader and one in the loop.

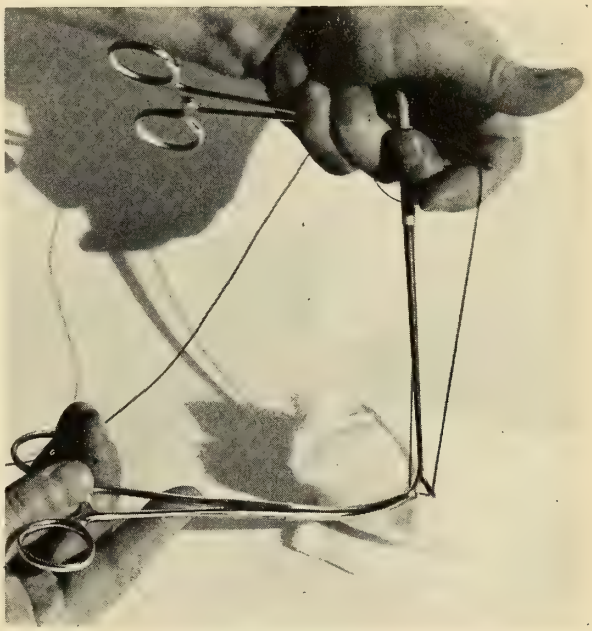

Fig. 4. One-hand tying after the knot is formed.

4. It is customary for an assistant to hold the hemostat during the placing of the ligature. However, at times there is such difficulty in manipulation that the surgeon himself must guide the point of the forceps with his right hand. In such cases the leaders of the ligature above the descending knot are clamped. Then, with the left hand grasping this clamp, and the finger

placed between the strands, the palm of that same hand presses down on the tier, simply completing the one-hand tie (Fig. 4).

Bleeders on the pillars must be handled quite delicately or muscle destruction will result. Need of hemostasis in these areas is rare in my experience.

After all ties are placed, a gentle roughening of the surface with a sponge is practiced in order to insure discovery of bleeders likely to open several hours later. This procedure brings to light potential postoperative hemorrhage often enough, I believe, to justify itself.

The use of the "Y" tier is easily adapted to local anesthesia tonsillectomies and may be applied during the first eighteen hours of the postoperative period.

Results

During the period covered by this study 200 tonsillectomies were performed under general anesthesia and 150 under local anesthesia.

In the group of 150 local anesthesia tonsillectomies there were two postoperative hemorrhages. One was due to a tie that had slipped in a patient, A. J. Fourteen hours postoperatively, the point was easily religated at the bedside, employing the usual technique. The second case was in a patient, G. P. No ties had been found necessary during the operation, the patient leaving the operating room with a dry field. Moderate bleeding appeared twelve hours later which required ligation at the bedside.

The occurrence of a single frank hemorrhage in this local anesthesia group shows the importance of the proper application of a tie. The other hemorrhage suggests the importance of extreme care in ligating small bleeders after tonsillectomy under local anesthesia, inasmuch as following disappearance of the edema of infiltration and loss of the adrenalin effect seemingly insignificant hemorrhages might become profuse.

In the group operated upon under general anesthesia, one hemorrhage in a patient, D. M., a child of six years, became apparent forty-eight hours following operation, but was moderate and ceased spontaneously. There were two other hemorrhages in this group, each occurring in a brother and sister operated on the same morning, but not occurring until eight days postoperatively. Each was controlled by pressure applied for eight hours, and was located in the lower pole where no ligatures had been applied. From observation of these two cases and of cases of delayed hemorrhage occurring in patients in charge of other physicians, I am inclined to the belief that delayed postoperative hemorrhage is not due to slough of tissue, but rather to a length of vessel detached from the bed, which not having been ligated sheds its clot and reopens at a later date.

It is to be noted that the formation of a postoperative clot denotes hemorrhage. Except for the three cases in which bleeding might have ceased spontaneously, there were no clots formed in the tonsillar beds. Postoperatively the presence of large clots adds to the pain.

Conclusions

1. Exposure of the raw tonsil bed following tonsillectomy is easily accomplished and necessary for proper hemostasis.

2. As in other surgery, meticulous ligation of bleeding vessels, without inclusion of excess tissue, results in absolute control of postoperative hemorrhage.

3. In 350 cases of tonsillectomy there were three immediate hemorrhages of little consequence and two hemorrhages occurring eight days postoperatively, all other cases presenting fresh beds free of clots.

4. A method has been presented of executing these procedures, the results of which seem to prove its worth.

MEDICINE IN THE CHANGING ORDER

The unsolved problems of public health and preventive medicine lie in the field of health protection and health promotion of the adult, particularly the young adult, who is the most productive member of society. It is also quite clear that problems of adult hygiene cannot be solved by the methods of mass approach.—Report, New York Academy Med. Comm., The Commonwealth Fund, 1947.

CERTAIN FACTORS INFLUENCING SURVIVAL AND DEATH IN CORONARY ARTERY DISEASE

FREDRICK A. WILLIUS, M.D.
Rochester, Minnesota

WITHIN the last decade and a half, a change occurred in the medical concept regarding the prognosis in coronary artery disease. The previously existent pessimism has been supplanted by a greater tone of optimism. This has been brought about by several attainments. More accurate and comprehensive studies of large groups of patients over long periods have yielded statistical information which has favorably modified the data elicited from previous limited investigations conducted over short periods. These short-term studies failed to reveal the true over-all picture, because the mortality rate of coronary artery disease is at its peak during the first year following the onset of symptoms. While the death rate successively continues, it does so in a gradual and less impressive manner. Thus, a study of a limited number of patients over a period of five years will obviously present a much higher relative mortality rate than a study of a large group of patients over a period of twenty-five years or more. Furthermore, greater diagnostic accuracy, the earlier positive recognition of the disease, and its more prompt and effective management have all been factors in the more favorable prognosis. It therefore seems appropriate to undertake an appraisal of the known factors which influence both survival and death in this remarkably common form of heart disease.

Coronary artery disease adapts itself to classification in two main categories: (1) transient recurrent episodes of coronary insufficiency, named angina pectoris by Heberden in 1772, and (2) sudden occlusion of one or more coronary arterial tributaries by thrombosis with or without acute infarction of the myocardium. The patients in either category may have the complicating effects of significant hypertension or associated cardiac defects.

Remarks on the Genesis of Coronary Artery Disease

While the exact genesis of arteriosclerosis and atherosclerosis is not known, certain pertinent speculations from observation and experience are justified. It has long been known that arteries or arterial junctions which normally are subjected to unusual stress and strain are favorite sites for the development of these changes. This is particularly true of the coronary arteries, and especially of the coronary tributaries which supply the left ventricle. Owing to the massive musculature of the left ventricle, the branches are deeply penetrating and they issue from the main artery at right angles, an arrangement which rhythmically, with the beat of the heart, permits buckling of the vessel to occur and renders these junctions susceptible to great and recurrent strain. Opposed to this status are the coronary tributaries which supply the right ventricle. The musculature of this chamber is less massive, the vessels are smaller and more superficial, do not penetrate the muscle mass at right angles, and are therefore not subjected to the same degree of strain as are those of the left ventricle. These observations are in harmony with postmortem findings.

From almost the beginning of medicine, atherosclerosis and arteriosclerosis have been accepted as concomitants of the process of aging. In so far as the venerable years of life are concerned, this may be true, but in the younger age groups another answer must be sought. Various investigations during recent years have shown that many patients with coronary artery disease, and with arteriosclerosis obliterans of the extremities, have associated hyperlipemia with or without lipoid deposits in the skin (xanthelasma). In this connection, the studies of Leary have been both interesting and important. He suggested that atherosclerosis represents a disturbance of the lipoid metabolism of the body and that thus, instead of being a normal aging process, it belongs to the category of metabolic diseases wherein animal fats are not properly utilized and excessive quantities of the lipoids are present in the blood and tissues of individuals, in a similar manner to the failure of carbohydrate metabolism in diabetes mellitus and failure of purine metabolism in gout.

Leary and others recognize three basic arterial lesions. The first is atheroma, which is a rever-

Read before the staff of St. Joseph's Hospital, Saint Paul, Minnesota, September 9, 1947.

sible process in youth, in which cholesterol esters appear in foam cells in the subendothelial layer of the intima, as in atherosclerosis. Excess cholesterol is removed by cells which have the general character of fibroblasts. In these cells, the esters are split, the excess cholesterol becomes dissolved and disappears, and excessive cholesterol does not remain sufficiently long to be an irritant and thus bring about true atherosclerosis. As the body ages, the power to remove excess cholesterol from the arteries apparently becomes lost. The second type of lesion is atherosclerosis, which is a progressive process in which the foam cells persist for long periods, and the excess cholesterol is retained, acts as an irritant and stimulates the growth of connective tissue. The third type is arteriosclerosis, which is the ultimate calcification of the already existing arterial lesions.

Cholesterol is a lipoid found in nature only in animal bodies and their products. It is a basic substance of every animal cell, and the human supply is derived solely by ingestion. It is not synthesized in carnivorous animals or man. It is probable that herbivora synthesize cholesterol from the closely related phytosterols, which have the same chemical formula as cholesterol but with a different molecular arrangement. Cholesterol occurs in both a visible (polariscopic) form and a combined nonvisible form. It has been shown that visible cholesterol normally occurs in the adrenal cortex, myelin sheaths, interstitial cells of the testicle and, at times, in corpora lutea. Otherwise, visible cholesterol appears always to be associated with disease. It is a chronic irritant and, like other foreign substances, tends to stimulate the growth of connective tissue.

Man is the only known creature who, from soon after birth to old age, partakes of a relatively high animal fat diet. Furthermore, man is the only known creature that dies relatively young from coronary disease and, as he attains advanced periods of life, universally exhibits arteriosclerosis. Also atherosclerosis has repeatedly been produced experimentally in herbivora by the feeding of rich cholesterol diets.

Difficulty has been encountered in explaining the sex discrepancy in coronary artery disease. There is a ratio of nearly 5:1, the disease being remarkably more common among men than among women, and when coronary artery disease does develop among women, it is usually later in life than among men. This fact cannot be explained on an anatomic or general physiologic basis, nor on the basis of occupational differences or other environmental factors. There is, in reality, only one fundamental functional difference between men and women, and that is woman's specific function of reproduction.[8]

It is a well-known fact that during pregnancy the lipoids of the tissues of the body increase markedly. This is without a doubt a physiologic response to assure adequate nutrition for the development of the fetus. However, when pregnancy has been resolved and the normal adjustments have been made, women in most instances are capable of mobilizing and utilizing this excess lipoid material and again assuming a condition of complete normality. Women are apparently possessed of a more perfect and active lipoid metabolism than men. When men once begin to accumulate lipoids in their tissues, the lipoids tend to remain there and frequently are deposited in the arterial intima.

In discussing the genesis of coronary artery disease, the influence of heredity cannot be avoided. It is a daily experience when one questions patients suffering from cardiovascular-renal disease that the development of various phases of this disease in successive generations of the family is not uncommon. There seems little doubt that a heredity of this type results in certain persons being born with relatively poor cardiovascular fabrics. Some of them, under more or less cloistered and protected conditions of life, may get along very well, but many others do not. The latter are at least candidates for coronary artery disease, hypertension or both.

In addition, the stresses and strains of modern life, which promote recurrent and finally sustained tension and often prevent adequate rest and relaxation, are undoubtedly important influences which favor the development of vasospasm in certain individuals. It is furthermore known that a complicating hypertension is capable of accelerating the progression of both the atherosclerotic and arteriosclerotic lesions.

Another factor which must be taken into account in this discussion is the question whether the use of tobacco accelerates the progression of coronary artery disease. There is an increasing tendency toward more widespread and excessive use of tobacco today. The general statement that the use of tobacco is injurious to all who practice the habit is, without a doubt, far from being

the truth. It, however, can be correctly stated that an appreciable group of individuals exist who do not tolerate tobacco well and among whom, under its continued and especially excessive use, episodes of vasospasm may occur.

In 1940, English, Berkson and I carried out a comprehensive statistical study regarding the use of tobacco in coronary artery disease. It is of interest to note that in the fifth decade of life, 79.7 per cent of the patients who had coronary artery disease were smokers and in the control series in which this disease was absent, 61.9 per cent were smokers. This is a discrepancy of approximately 18 per cent and is of significant statistical importance. Data of this nature obviously do not permit the conclusion that tobacco is a specific agent in the genesis of coronary artery disease, although the allegation cannot be denied that it may accelerate the arterial lesions in some persons, particularly when excessively used. It seems, therefore, that tobacco has its greatest injurious potentialities in the younger age groups. The effect of the degree of smoking was also investigated, and it became evident that the incidence of coronary artery disease increased with the degree of smoking.

Transient Recurrent Episodes of Coronary Insufficiency (Angina Pectoris)

It is desirable to analyze this group of patients first because they may be stated to represent the uncomplicated form of coronary artery disease. In many of them, sudden occlusion of a coronary arterial tributary has not occurred, although these individuals are perpetual candidates for this complication to happen at some time. It is a well-known fact that the coronary arteries of patients in this category are commonly obstructed or at least considerably narrowed by atherosclerosis or arteriosclerosis, but the obliterative process has occurred gradually rather than suddenly. The obliterative process commonly involves multiple tributaries.

This gradual narrowing and occluding process, usually extending over a period of several years, is the impetus for the development of collateral circulation, the basic mechanism whereby survival is possible. Most human hearts are provided with a variable abundance of small nonfunctional channels which become functional and intercommunicating when the demand is imposed. Collateral circulation may be well established and adequate by the time that complete closure of a coronary artery occurs but, more frequently, it is inadequate and incompletely established. This collateral circulation, bridging the gap of an occluded artery, is gradual in its development and may not reach its potential maximum for several years. In certain instances, its adequacy becomes so complete that with reasonable care the patient becomes free of symptoms. However, many other patients, by perpetually limiting excessive demands on the heart, may remain relatively free from symptoms even though the coronary circulation is limited.

The tendency exists for coronary atherosclerosis and arteriosclerosis to be a progressive process, although numerous instances occur in which the progression is gradual and at times favorably counteracted by the ultimate establishment of remarkably adequate collateral circulation. These are largely the patients who survive the disease beyond the critical first year period.

It is of great importance that the diagnosis of coronary artery disease be made promptly in order that a proper individualized regimen can be introduced immediately. I am convinced that the properly ordered regimen, when obeyed, is of paramount importance in the survival of many patients. Advice must center around modifications or prohibitions aimed at completely controlling the symptoms if possible. The advice naturally varies from patient to patient. Owing to the fact that the first year of the disease as evidenced by symptoms is so important, the immediate institution of the regimen should not be delayed. Temporary discontinuation of work in the form of a restful vacation at home should be insisted on whenever possible. It is almost the rule that the onset of symptoms coincides with bouts of unaccustomed activity, tension and fatigue. The patient must acquire a new philosophy of life, an accomplishment which rarely can be achieved in a short time. He must learn his physical tolerance, he must learn the art of relaxation, and, above all, learn to control his emotions more adequately. It is of great importance that the patient be instructed to modify his activities below his limit of accustomed tolerance during extremely hot weather, particularly when the humidity is high, during extremely cold weather and during periods when abrupt and great fluctuations of temperature occur. Each patient should be instructed regarding the use of nitrites and should always have the

drug on his person for immediate use if necessary. The obese patient should reduce his weight by careful dietary precautions, and the excessive smoker should either discontinue the use of tobacco or use it sparingly. Patients who have hyperlipemia should use animal fats very sparingly in their diets, but unfortunately this method is frequently not effective. The use of the xanthine derivatives, vitamin concentrates and countless other so-called modern agents has been quite ineffective and has certainly not modified the course of the disease. Mild sedation has a definite place in certain patients.

Sudden thrombotic occlusion of a coronary arterial tributary in this group of patients commonly eventuates in sudden or ultimate death. Here again, the time factor enters the problem significantly because, if enough time has elapsed from the onset of symptoms of coronary insufficiency to permit adequate collateral circulation to become established, a complication that otherwise would be fatal may prove to be only a temporarily disabling incident.

The problem of sudden death during transient episodes of coronary insufficiency, in the absence of thrombotic occlusion and acute myocardial infarction or without complete atheromatous or arteriosclerotic obliteration of a coronary arterial tributary, remains largely unanswered. It is, however, not improbable that sudden and somewhat prolonged periods of myocardial anoxia are capable of initiating marked and often fatal disturbances in the intrinsic mechanism of the heart, such as ventricular fibrillation, ventricular tachycardia, asystole and even profound and irreversible disturbances of conduction. The abrupt termination of life under such circumstances has not, except in rare instances, permitted physicians to suspect these events by means of auscultation or to prove their occurrence by graphic records.

Recurrent thrombotic occlusion of coronary arterial tributaries obviously reduces the chances of survival. Cardiac enlargement is also an unfavorable finding regardless of its cause. It may result from hypertension, from multiple healed or healing infarcts, or from associated unrelated cardiac lesions. One or more episodes of congestive failure or bouts of pulmonary edema are invariably of grave import and rarely coincide with even a limited expectation of life. The same is true of the so-called status anginosus, always an expression of extensive, severe and progressive involvement of the coronary arterial tree.

In the discussion relating to the unfavorable import of congestive heart failure, brief comment regarding the oft-neglected venous coronary circulation is appropriate. Katz and his associates studied the venous coronary circulation in 1938 and made important contributions. Their work indicated that an average of 92 per cent of the blood from the right circumflex artery drains into the right thebesian system, while the coronary sinus receives an average of only 1 per cent and the left thebesian system an average of 7 per cent of the blood. In the case of the left circumflex artery, the right thebesian system drains an average of 48 per cent of the blood, the coronary sinus an average of 38 per cent, and the left thebesian system, 14 per cent of the blood. The anterior descending branch of the left coronary artery drains an average of 51 per cent of its blood into the right thebesian system, an average of 42 per cent by way of the coronary sinus, and an average of 7 per cent into the left thebesian system. These studies show the importance of the right thebesian system as a drainage bed, even of the blood from the arteries of the left side of the heart. Thus, approximately two thirds of the total blood flowing through these three important coronary arteries drains into the right thebesian system and less than one third into the coronary sinus. It therefore becomes evident that interference with this important drainage bed, such as occurs in congestive heart failure when pressure within the right ventricle becomes significantly increased, immediately impairs the efficiency of the coronary arterial blood flow.

Finally, the absence of significant electrocardiographic alterations tends to indicate a more favorable prognosis than their presence indicates, although many exceptions to this statement have been observed. Approximately a third of patients with transient recurrent episodes of coronary insufficiency, who have escaped sudden thrombotic occlusion and in whom significant hypertension is absent, have essentially normal electrocardiograms. This finding, however, must never be interpreted as mitigating, in any sense of the word, the importance and potential seriousness of the disease. By the same token, abnormal electrocardiograms do not necessarily or always indicate a grave prognosis, although many physicians make such inferences on very flimsy and

speculative evidence. After all, the question of survival or death rests fundamentally on the functional adequacy of a structurally impaired coronary circulation.

Sudden Occlusion of One or More Coronary Arterial Tributaries by Thrombosis with or without Acute Infarction of the Myocardium

The abrupt occlusion of a coronary arterial tributary frequently occurs as the first manifestation of coronary artery disease. However, atherosclerotic or arteriosclerotic changes in one or more vessels have been present, but many times the coronary circulation has not been impaired to the degree where symptoms have occurred. Therefore, the event commonly occurs with dramatic suddenness, the pre-existing arterial lesion may comprise only a limited segment (the so-called plaque), and death may occur immediately or soon after the complete closure of the arterial tributary occurs. This is in part due to the fact that the preparatory mechanism instrumental in fostering the development of collateral circulation has been absent.

The most common basis for the abrupt closure of a coronary arterial tributary is thrombosis, usually occurring near or at the point of arterial narrowing and roughening. Less commonly, hemorrhagic lesions in the walls of the coronary arteries are the forerunners for abrupt vascular occlusion usually completed by regional thrombosis. In 1943, English and I reported our findings in 135 hearts secured at postmortem examination. Hemorrhagic lesions were discovered in the walls of the coronary arteries in 40 per cent of the specimens examined and were directly or indirectly related to abrupt closure of the vessel in 39 per cent of the hearts exhibiting such lesions. The lesions were characterized by hemorrhage, the presence of large lipoid-containing cells (foam cells), proliferative intimal changes and organization. Smaller and less active lesions were found adjacent to calcified plaques. The intimal changes which coexisted with the hemorrhage appeared to represent the primary factor in the process, while the hemorrhage was a secondary event.

Very rarely, coronary embolism from a more or less remote thrombotic focus is the basis for sudden coronary obstruction. This event most frequently occurs where the coronary arteries are relatively normal, most commonly from valvular vegetations or mural thrombi situated in the left chambers of the heart, and only rarely as a paradoxical embolism from some focus in the right chambers of the heart or in the venous system.

The myocardial response to abrupt coronary artery closure is usually acute infarction. However, under conditions of pre-existing symptoms of recurrent transient coronary insufficiency, particularly when they have existed for a considerable time and the patient has survived the critical period during which collateral circulation is being established, sudden thrombotic closure of a coronary tributary may not result in myocardial infarction. While this circumstance is relatively rare, its reality has been definitely established by careful postmortem study.

When the patient survives the immediate impact of sudden coronary occlusion, and certain complicating features, such as intraventricular mural thrombosis with embolic detachments, spontaneous rupture of the infarcted region, and profound disturbances of rhythm, do not occur, an excellent chance for survival is afforded. This statement is of course predicated on the supposition that prompt and adequate rest and treatment have been inaugurated.

The complete healing and cicatrization of an infarct cover approximately a period of three months although considerable repair usually is evident within a month. It is, therefore, of great importance that complete rest be enforced during the early phases of recovery. When the process of infarction is completed, which usually occurs within forty-eight to seventy-two hours, nature's first task is to remove the necrotic detritus, which is accomplished by phagocytosis. This process results in a variable degree of leukocytosis and acceleration of the sedimentation rate of the erythrocytes. Frequently, within twenty-four to forty-eight hours, an invasion of fibroblasts occurs, best seen at the margins of the infarct. This process represents the first stage of healing. A little later small blood vessels are observed accompanying the new fibroblastic growth. These new vessels obviously furnish a system of transportation and nutrition for the healing infarct. They are in no sense components of the functional collateral circulation, already discussed, but apparently serve only to promote healing of the infarcted region. In large infarcts, particularly where collateral circulation has not been established to a functional degree, and conditions of

potential healing are absent, interrupted or delayed, progressive necrosis of the infarcted region occurs with spontaneous rupture or aneurysmal dilatation of the affected portion of the left ventricle. The former complication usually terminates in sudden death, although a period of several hours from the time of perforation until dissolution has been observed. In the latter complication, death may occur suddenly or gradually. As previously stated, recurrent multiple infarcts obviously diminish the patient's chances for survival.

In the attempt to prevent the occurrence of mural intracardiac thrombosis in acute cardiac infarction and to prevent extension and recurrence of the intra-arterial thrombosis, the virtually routine employment of anticoagulants has been introduced. Usually the administration of heparin is recommended during the first twenty-four hours to achieve prompt action, with the simultaneous administration of dicumarol to effect sustained action after the discontinuance of administration of heparin. While the total experience gleaned by this method of treatment is still too limited to enable one to draw positive conclusions, the incidence, particularly of embolic phenomena, appears to have been significantly reduced. The use of anticoagulants in patients prior to acute coronary occlusion is as yet not to be advised because no comprehensive data exist to recommend it and, owing to the necessity of constant medical vigilance, it appears at this time to be impractical.

The location of the cardiac infarct, with the exception of quite extensive involvement of the interventricular septum, does not seem to influence survival or death materially. The size of the infarct does clearly affect the outcome.

In most human hearts the general scheme of the coronary arterial tree varies little with the exception of minor differences. However, from time to time, specimens are observed in which congenital anomalies of the coronary vessels have afforded the patient no chance whatsoever to survive, even temporarily, the sudden occlusion of a main arterial tributary. In this discussion I shall not consider those marked anomalies, frequently associated with other congenital cardiac defects, where, for instance, the coronary arteries, instead of arising from the aorta, issue from the pulmonary artery. However, anomalies of the coronary arterial tree do exist which, in the absence of a significant obliterative arterial lesion, permit a restricted circulation and function. In this category are the few cases recorded in medical literature in which a single coronary artery supplied the entire heart. Its abrupt occlusion obviously would terminate in sudden death. More commonly, the entire posterior and lateral aspects of the left ventricle and a portion of the apex are supplied by branches of the right coronary artery in the congenital absence of the left circumflex coronary artery. Instances have also been observed in which the right coronary artery in no degree supplied the posterior aspect of the left ventricle (which it normally does) and, therefore, all of the left ventricle, except the anterior aspect and a portion of the apex, was entirely supplied by an overdeveloped left circumflex artery. Therefore, in either event, the sudden occlusion of such an anomalous artery would certainly not be conducive to survival. At the present time, no positive clinical method exists for the identification of these anomalies, although the occurrence of transient recurrent episodes of coronary insufficiency in children or young adults should always recall to mind the possibility of the condition.

As in the cases of coronary artery disease in which thrombotic occlusion has not occurred, the patients who have acute myocardial infarction are candidates for sudden death from profound disturbances of rhythm, such as ventricular fibrillation, ventricular tachycardia and asystole. It has been suggested that under these circumstances foci of increased irritability arise in the junctional zone of myocardium between the infarct and normal cardiac muscle. However, likewise in these cases, the incidence of profound disturbances of rhythm is not known, because rarely does the element of time permit graphic registration of the activity of the heart. Where extensive infarction of the interventricular septum occurs, complete heart block with or without convulsive syncope may occur soon after the occlusion and eventuate in death in a few hours or days.

It is not an uncommon observation that patients who survive sudden thrombotic occlusion of a coronary tributary and in whom transient recurrent episodes of coronary insufficiency had previously occurred, may entirely lose their painful seizures. This is explained by the fact that a new obstructive lesion has given added impetus to the developing collateral circulation.

In order to amplify my opening statement concerning the more optimistic present-day concept

of the prognosis in coronary artery disease, I shall cite briefly from the recent study of Parker, Dry, Willius and Gage. The survival rates of patients having transient recurrent episodes of coronary insufficiency (angina pectoris) were determined for a group of 3,400 patients who were examined at the Mayo Clinic over a period of twenty years and for whom follow-up data could be secured.

All survival rates of the patients in the study were compared with the survival rates of a comparable group of the normal population having the same age and sex distribution. This control is obviously the necessary yardstick for comparative study.

The highest mortality rate occurred in the first year following the establishment of the diagnosis of coronary artery disease. Thereafter the yearly mortality rate was less, although it continued relentlessly yearly throughout time. The survival rates of women were greater than those of men.

When corrected for deaths not due to coronary artery disease, the five year survival rate of patients thirty to thirty-nine years of age is definitely less than when the disease manifests itself later in life. This fact is probably based on the inadequate development of collateral circulation in the younger age groups.

Such associated conditions as cardiac hypertrophy, significant hypertension, previous cardiac infarction, congestive heart failure and significant electrocardiographic abnormalities are clearly related to a higher mortality rate and a lower survival rate.

The perfect statistical study has as yet not been conducted. Complete and, therefore, precise data cannot be ascertained until every patient in the selected group has died. My younger colleagues are dedicated to the ultimate completion of this particular investigation.

In this discussion I have considered the known factors which influence survival and death in coronary artery disease. There remains no doubt that numerous unknown factors exist. When the time comes that more conclusive knowledge relating to the genesis of atherosclerosis and arteriosclerosis with special reference to the coronary arteries is available, then perhaps active steps can be undertaken both in childhood and adult life at least to diminish the incidence of the disease and perhaps to prolong the lives of patients afflicted.

THE DRUG ADDICT

(Continued from Page 484)

eral Narcotic Bureau is referred to the Minnesota State Board of Medical Examiners for investigation and disposition. If the physician is willing to be hospitalized under the care of a competent medical man of his own selection, until he has made an apparent recovery, no further action will be taken. He will probably be temporarily deprived of his narcotic permit, and if there is a recurrence his license to practice medicine may be rescinded. This arrangement with the Federal Narcotic Bureau is fortunate, indeed, as it gives Minnesota an opportunity to supervise and treat its own physicians who become so afflicted. Furthermore, the physician can be treated in a Minnesota hospital by a physician of his own choice, instead of being sent to the United States Public Health Service Hospital in Lexington, Kentucky.

COLD PREVENTION STUDY

Influenza Vaccine for the Prevention of the Common Cold

DONALD W. COWAN, M.D., and HAROLD S. DIEHL, M.D.
Minneapolis, Minnesota

REPORTS from various sources that influenza vaccine seems to prevent attacks of the "common cold" led us to set up a simple experiment to test the possible effectiveness of influenza vaccine in this regard. Fortunately, this study was made during the winter of 1946-47 when there was relatively little influenza in this area. Therefore, the effectiveness of the influenza vaccine in preventing influenza itself was not a complicating factor in analyzing the results of this study.

The experimental subjects were University of Minnesota students. The technique of the study was the same as that followed in our previous cold prevention studies.[1-4] Early in October, 1946, there were 666 subjects enrolled in the study. They were unselected, except that it was made known that we wanted persons who were especially susceptible to colds. After receiving instructions, and after each student had filled in the questionnaire concerning the previous experience with colds, he or she was given a single injection. As an experimental group, 346 subjects received 1 c.c. of standard influenza A and B virus vaccine.* Serving as a control group, 320 students received 1 c.c. of sterile physiological saline solution. None of these students knew the nature of the injection received. Following the injection, the students were questioned periodically by questionnaire cards. Of the original 666 who were enrolled, 480 completed the study. Some of the losses were due to cancellation from school, others to lack of co-operation in the matter of reporting, and a few were eliminated from the group because their "colds" appeared to be mainly of an allergic nature.

Table I summarizes the results of the experiment. It will be noted that the vaccinated group had essentially the same number of colds as the control group during the period of the study: 2.9 colds per person and 3.0 colds per person, respectively. If one compares these numbers with the average number of colds which the students reported that they had had during the previous year, one finds that they represent a reduction of 47 per cent for those receiving the influenza vaccine and 41 per cent for those receiving the saline. It must be remembered, however, that these figures for percentage reduction are based upon the students' memories as to how many colds they had had in previous years. The fact that memories are not too reliable in this regard is indicated by the fact that many could not even recall at the end of the study how many colds they had had during the period of the study. The effect of this for the group as a whole is shown in Table II. The left hand column for each group represents the number of colds reported by the students on their periodic reports submitted during the study. The right hand column represents the answers which the same students gave to a question which appeared only on the final report. This question

TABLE I. COLD PREVENTION WITH INFLUENZA VACCINE

	Vaccine Group	Control Group
Subjects who began study	346	320
Subjects who completed study	252	228
Percentage who completed study	72.8%	71.2%
*Number of colds per person during previous year (average)	5.5	5.1
Number of colds per person during period of study (average)	2.9	3.0
Difference between average number of colds in experimental and control groups		
Number of days per person lost from school (average)	.7	.9
Percentage of group who had no colds during year	4.0%	6.6%
**Percentage of students with colds in which complications developed	19.8%	21.0%
Percentage sent to infirmary with colds or complications	1.6%	.9%
Total days in bed per 100 students in group	101.2	128.3
†Severity of colds, percentage of total colds for each group		
Mild	59.2%	59.8%
Severe	33.8%	33.9%
Very severe	6.9%	6.3%
†"Helpfulness" of vaccination, percentage of total answers		
Helpful	50.8%	51.8%
Not helpful	19.8%	22.8%
No answer	29.4%	25.4%

*Reported from memory.
**Sinusitis, otitis, bronchitis, pneumonia, et cetera. (as reported by student).
†As judged by the student himself.

TABLE II. ACCURACY OF REPORTING COLDS

	Total Colds Reported on 3 Interim Reports	Total Colds for Year as Reported at End of Study
	Vaccine Group	
Total	483	581
No. of Cases	181	181
	Control Group	
Total	499	590
No. of Cases	176	176

*Furnished from the U. S. Army supply by Service of Preventive Medicine, Office of Surgeon General, U. S. Army, through Dr. Thomas Francis, Jr., director of Commission on Influenza, Army Epidemiological Board.

asked how many colds they had had during the entire period of study. Since not all of the students answered this final question, Table II is made up on the basis of 181 subjects for the influenza vaccine group and 176 for the control group. Each group over-estimated by roughly 20 per cent.

Because of the possibility that the vaccine might have been effective soon after its administration but not later, the experience of the two groups was compared by "quarters." These quarters are not of equal length because of the necessity of getting the last report before the students started their final examinations. The first quarter extended from early October to January 6, the second quarter from January 7 to April 1, and the third from April 2 to May 15. Table III shows that this breakdown by quarters reveals no evidence of any effectiveness of the influenza vaccine in the prevention of the common cold at any time during the entire period.

TABLE III. NUMBER OF COLDS BY QUARTERS

Quarter	I	II	III
Vaccine Group Average number of colds per person	1.2	1.2	.5
Control Group Average number of colds per person	1.2	1.2	.6

On the periodic report, the students indicated whether, in their opinion, the colds that they had had during the study were mild, severe, or very severe; Table I shows that there is no difference between the vaccinated group and the control group in this regard. They also were asked to indicate on each report whether they believed that the injection they received had been helpful in preventing colds. It will be noted that roughly half of each group and 70 per cent of those who answered this question replied that they believed that the injections had been helpful.

Reactions from Influenza Vaccination

One week after the vaccination had been accomplished, cards were sent to the students asking about reactions which might have been caused by the injections which they had received. The reports are tabulated in Table IV. This is the only tabulation that shows any difference between the vaccinated and the control groups. In addition to the reactions listed, several others were written in, but of these the only one of importance was generalized urticaria reported by one subject who had received the influenza vaccine. Of special interest are the "reactions" reported by those who received the injections of physiological saline. This indicates that even in this matter a base line must be drawn when considering the reactions to an injection.

TABLE IV. REACTIONS TO VACCINATION IN COLD PREVENTION GROUP

	Vaccine Group N=320 Per Cent	Control Group N=305 Per Cent
No reaction	16.2	78.0
Sore arm	78.4	9.2
Headache	16.9	9.2
Backache	5.9	.3
General aches and pains	14.1	3.3
Chill	10.6	1.6
Fever	14.4	5.6
Incapacitated	6.9	1.0
Days lost, school or work	.06	.01
Days in bed	.06	.01

TABLE V. REACTIONS TO INFLUENZA VACCINE FROM DIFFERENT MANUFACTURERS

	"Influenza Prevention" (Influenza Vaccine by manufacturer X) N=1952* Per Cent	"Cold Prevention" (Influenza Vaccine by manufacturer Y) N=320 Per Cent
No reaction	12.8	16.2
Sore arm	79.9	78.4
Headache	26.2	16.9
Backache	11.7	5.9
General aches and pains	25.2	14.1
Chill	16.1	10.6
Fever	21.4	14.4
Incapacitated	14.0	6.9
Days lost, school or work	.08	.06
Days in bed	.10	.06

*The average age of the persons in the first column, since it included some University faculty members and employes, is a little greater than the average of those in the second column.

It was found, incidentally, that reactions to influenza vaccine varied according to the make of the product, even though the vaccines were made by the same process. At the University Health Service, a considerable number of students, faculty members, and employes were given influenza vaccine at about the same time that this cold prevention study was inaugurated. Practically all the vaccine used for this large group was made by manufacturer X, whereas the influenza vaccine used for the cold prevention study and furnished us by the Influenza Commission of the U. S. Army was made by manufacturerY. Table V compares the reports of 1,952 of the former group who replied to our questionnarie with the reports of the students in the cold prevention study who received influenza vaccine.

CLINICAL-PATHOLOGICAL CONFERENCE

OMPHALOCELE

O. W. ROWE, M.D., R. C. PEDERSON, M.D., and A. H. WELLS, M.D.
Duluth, Minnesota

Dr. A. H. Wells: Omphalocele is a congenital protrusion of abdominal viscera into the umbilical cord. The lesion is referred to by a variety of synonyms including congenital umbilical hernia, exomphalocele, hernia funiculi umbilicalis, ectopia viscerum, amniotic hernia, amniotic umbilicus, amniocele, and coeloma funiculi umbilicalis persistence. We are presenting a series of five cases of omphalocele representing some of the extremes of this congenital abnormality. Undoubtedly, a better knowledge of this type of hernia will result in a much higher percentage of survival.

Case Presentations

Case 1

Dr. R. C. Pedersen: A full-term, spontaneously delivered, 6 pound 13 ounce, white baby girl (Case 3666) appeared perfectly healthy at the time of birth on March 5, except for a bulging umbilical cord hernia (Fig. 1) measuring from 6 to 8 cm. in diameter. Pediatric consultation led to the use of sulfa powder and sterile dressings over the translucent hernial sac. An operation did not seem to be immediately advisable. After forty-eight hours, the infant's color became very poor, with obvious cyanosis of the lips and fingers. This cyanosis continued with periods of improvement, until her death. Continuous oxygen therapy was started on March 10. The infant took her feedings well, and although repeated x-ray examinations failed to reveal pulmonary disease, penicillin was given. The white blood count was 12,600 with 50 per cent neutrophiles. There were 4,300,000 red blood cells and 15 gm. of hemoglobin. Respirations were 97 per minute. There was a low grade fever, the temperature ranging from normal to 101° F. In spite of the recognized poor prognosis, it was deemed necessary to repair the umbilical cord hernia surgically, since there was obvious beginning gangrene of the tissue-paper-like covering of this structure. On March 15, under ether-oxygen endotracheal anesthesia, a complete circular incision around the defect in the anterior abdominal wall led to the removal of degenerating necrotic coverings of the hernia and a return of the liver tissue, which completely filled this sac, into the abdominal cavity. The fascia and skin were closed over the defect.

The infant's respirations remained rapid at 90 per minute. Her temperature rose to 102° F. She continued to have cyanosis and coughed occasionally. She expired forty-eight hours postoperatively, at the age of twelve days.

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota.

Fig. 1. *(above)* Omphalocele with a drying amniotic membrane.
Fig. 2. *(below)* Opened huge omphalocele containing nearly all the abdominal viscera.

Dr. A. H. Wells: This newborn white female infant weighed 2,830 gm. and measured 48 cm. in length. There was a good deposit of subcutaneous fat, and there were no congenital abnormalities apparent on the external surface. A recently sutured operative wound at the umbilical site was intact and free from healing and suppuration. There were flakes of fibrinous exudate over serosal surfaces throughout the peritoneal cavity, cultures of which revealed hemolytic Staphylococcus aureus.

This exudate also covered a remarkably congenitally deformed liver which could be divided into two parts of approximately equal size. One portion, represented by the right hand portion of the left lobe, had a normal contour, but was about half the usual size of these parts of the liver. A globular pedunculated mass of liver tissue, measuring 3 by 3 by 4 cm., hung by a pedicle from the left lobe of the liver and represented the portion of liver tissue which had protruded into the omphalocele and was surgically returned to the peritoneal cavity. A thin flat pedicle of fibrous tissue, measuring 2.5 cm. broad and 5 mm. in thickness, separated the left lobe from the herniated portion. The gall bladder and its ducts were not unusual. There was a mottled congestion and approximately 20 per cent atelectasis of the lobes of both lungs, which revealed many small clumps of pus cells and many squamae scattered through air spaces and bronchioles of histologic sections. The final diagnosis was omphalocele containing a congenitally deformed left lobe of the liver, with surgical correction, generalized peritonitis and bronchopneumonia.

Case 2

Dr. O. W. Rowe: A seven-day-old white male infant was referred to me in a critical condition with a huge omphalocele, the size of a large orange. The hernia was covered with an extremely thin translucent membrane which was beginning to turn black in places. The child was quite dehydrated. After preliminary efforts at restoration of fluids and electrolyte balance, on June 19, twenty-four hours after admission, the hernia was repaired by Dr. Oswald Wyatt of Minneapolis at St. Mary's Hospital in Duluth. Under drop ether anesthesia, an incision was made circling the umbilical mass and extending down into the peritoneal cavity. The hernia was found to contain almost the entire mass of small bowel and the entire left lobe of the liver which was extremely swollen and edematous (Fig. 2). The round ligament containing the umbilical vein was divided and ligated. The small bowel and liver were slightly adherent to the edge of the hernial defect and were freed up by blunt dissection. With difficulty, it was possible to reduce and replace the liver and push it up under the diaphragm. With great effort and manipulation, the small bowel was finally returned to the abdominal cavity; however, the margins could not be approximated, so that the opening was closed by skin alone, using interrupted cotton through-and-through sutures. It was possible to close the peritoneum only for a short distance at the extreme upper end of the wound. There was a postoperative fever reaching as high as 101° F. Transfusions, intravenous subcutaneous fluids and antibiotics supplemented the surgical procedure. On June 25 the secondary operation of closure of the peritoneal cavity was accomplished without too much tension. There followed a long period in which it was extremely difficult to maintain fluid and electrolyte balance and feed the child. Efforts were finally successful and the child was discharged in good condition. On December 17 the referring physician, Dr. Closuit, reported that the patient was in excellent condition.

Case 3

Dr. E. Zupanc: This was a spontaneously delivered, anencephalic, stillborn, white female infant, approximately 3 months premature—a patient of Dr. Ralph Eckman. The thirty-six-year-old mother, gravida II, had had some nausea and vomiting for three months prior to delivery.

Fig. 3. Huge defect of the abdominal wall and the omphalocele covered by a transparent amniotic membrane.

Dr. A. H. Wells: This female anencephalic fetus, 23 cm. in length and weighing 720 gm., was attached to a 350 gm. placenta by a short umbilical cord (Fig. 3). Most of the abdominal viscera protruded into a huge omphalocele, including the liver, spleen, and nearly all of the small and large intestines. Other congenital anomalies included lumbar myelomeningocele, almost complete absence of the brain and spinal cord, and bilateral club feet.

Case 4

Dr. E. Zupanc: This "slightly premature" white male infant was delivered spontaneously in a Superior, Wisconsin, hospital by Dr. H. A. Sincock. The infant lived for a few minutes after birth.

Dr. A. H. Wells: A premature white male infant, weighing 1,350 gm., and 36 cm. in length, was attached to a placenta of average size by a 15 cm. in length umbilical cord (Fig. 4). At the base of the cord, the

amniotic membrane was continued as the only covering of a huge defect in the anterior abdominal wall, into which protruded the liver, stomach, small intestines and 75 per cent of the colon. The defect involved approximately half of the anterior abdominal wall, including

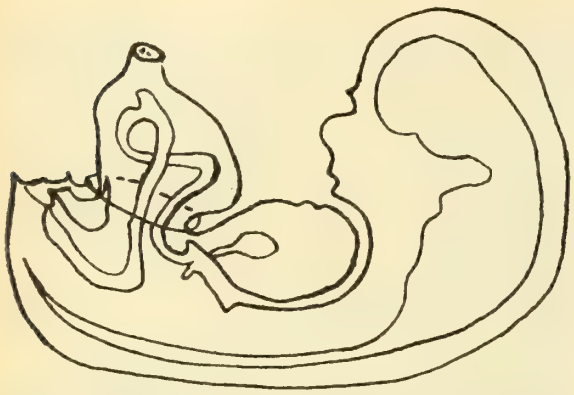

Fig. 4. Schematic drawing to show physiologic herniation of the mid-gut into the exoceloma.

most of the right side and superpubic area. In addition, there was a complete spina bifida, lumbar myelomeningocele, and bilateral club feet.

Case 5

Dr. E. Zupanc: This three month premature, white, stillborn female (Case 4062) was spontaneously delivered after an easy labor. The thirty-seven-year-old mother, a patient of Dr. R. J. Moe, had had no complications of pregnancy.

Dr. A. H. Wells: This premature, typically anencephalic infant measured 28 cm. in length and weighed 860 gm. The omphalocele was similar to that of Case 3 (Fig. 3). It measured 8 cm. in diameter, and the short umbilical cord was 15 cm. in length. The hernia contained the stomach, liver, spleen, small intestines, and all of the colon except the sigmoid. The abdominal cavity was extremely small. Other deformities were an absence of brain and spinal cord and a complete spina bifida.

Embryologic Etiology

Dr. A. H. Wells: In the normal process of development of the abdominal cavity and its contents, there appears a physiologic umbilical hernia, or exoceloma, at the fourth week of embryonic life, into which the mid-gut protrudes (Fig. 4). This is apparently due to increased intra-abdominal pressure at that time. At three months there is a reposition and an obliteration of the exoceloma, possibly due to decreased intra-abdominal pressure. It would then seem that an omphalocele is an arrested embryonic development, similar to the majority of the other congenital defects to which man is subject. In extreme form, there appears to be an interrelationship with abnormalities of development of whole sections of the abdominal wall, the liver and diaphragm. It has been suggested that a hyperlordosis of the spinal column could be a factor in the intra-uterine development of omphalocele. There have been references[3,4] to successive infants of the same parents having this umbilical defect. In a series of ninety-one cases[11] of omphalocele, more than one congenital defect occurred in one third of the cases. These included Meckel's diverticulum, atresia of the descending colon, spina bifida, rotation of the large intestines, epispadias, absence of common duct, macroglossia, cleft palate, hare lip, patent omphaloenteric duct, mongoloid, imperforate anus, stenosis of colon, microcephaly hydramnion, absence of tibia and absence of radius and ulna. Omphalocele is described as occurring in from 1 in 5,000[7] to 1 in 10,000.[6] Twelve cases were described as the Public Maternity Hospital at Stockholm in 120,000 births.[8] There are approximately 400 cases recorded in the literature.[12] The sexes appear to be equally involved.[6,8]

Pathology

Umbilical cord herniae have been classified depending upon their size, contents, theoretical etiology and the extent of eventration of the adjacent abdominal wall. The lesion can vary up to the size of a child's head. In one report,[11] fifty-two cases measured less than 5 cm. in diameter, and twenty-six measured more than 5 cm. Forty-five of 155 cases contained liver in the hernial sac along with other viscera.[7] The liver alone in the sac similar to our first case has been considered rare.[10] Portions of the small and large intestines, spleen and stomach are frequently found in the sac, and rarely the heart, kidney, uterus, ovaries and omentum have been found in the hernia.[7] The defect in the adjacent abdominal wall may involve a large portion of this wall similar to our Case 4. The hernia may be so large as to interfere with labor[7] or so small as to be tied off with the umbilical tape at the time of birth.[8]

Treatment

Except for the smallest omphaloceles, there is almost unanimous agreement that surgical repair at the earliest possible moment is the treatment of choice.[2,5,9] The amniotic membrane covering the umbilical cord and the hernia within the cord is a nonvital structure which soon dries out and becomes gangrenous, permitting the entrance of bacteria into the hernia and the peritoneal cavity. Of fifty-six cases[11] repaired in the first twelve hours, 21.4 expired; of nine cases operated upon between twelve and twenty-four hours, 44.4 per cent expired; and of thirteen cases operated after twenty-four hours, 61.6 per cent expired. The important factors determining the prognosis are the diameter of the defect, the size of the hernia and delay of the operation. Newborn infants are said to tolerate the shock of anesthesia and operation satisfactorily.[9] Of forty-five cases[7] containing a portion of liver, eleven recovered. The usual procedure is to excise the hernial sac back into the margins of normal skin, return the contents of the hernia into the abdominal cavity and close the abdominal wall. Care should be exercised not to increase the intra-abdominal pressure too extensively. If there is danger of this, then the

abdominal wall fascia should be left open and the skin alone closed over the defect.

Later the peritoneum and fascial sheaths of the abdominal wall can be more easily approximated. Respiratory embarrassment, paralytic ileus, displacement of the heart and large vessels or compression of the inferior vena cava are the common complications resulting from excessive intra-abdominal pressure.[6,8,9] A possible patent urachus should be kept in mind at the time of surgical repair to avoid a urinary bladder fistula. Coexisting serious congenital abnormalities may render a surgical repair of the omphalocele futile.

Conclusions

Five cases of omphalocele have been presented. In one, the hernia was filled with a portion of the left lobe of the liver. The full-term infant expired on the twelfth postnatal day, two days after a surgical repair of the hernia, as the result of acute generalized peritonitis and bronchopneumonia. There was a surgical repair of a large umbilical cord hernia of the second case on the eighth postnatal day. Because of a disproportion between the size of the abdominal cavity and the hernial contents, the surgical opening could only be closed with skin. Subsequent closure of the entire abdominal wall led to a cure. The last three cases were infants who were stillborn or who lived only a few minutes. They had huge hernias, one of which had an associated extensive defect of the abdominal wall covered by amniotic membrane. All three had multiple other serious congenital anomalies. The embryology, pathology and treatment of omphalocele has been briefly discussed with references to the literature.

Case Report

CEREBELLAR ABSCESS

Recovery Following Chemotherapy

CHARLES M. JESSICO, M.D.
Duluth, Minnesota

CONSIDERABLE speculation is possible in the case to be presented, and opinions as to what took place may differ. Early chemotherapy and susceptibility of the involved organism to the drugs used were undoubtedly very important factors in the good results obtained. This case is considered to be of special interest because there was no surgical intervention. Pilcher and Meacham in Spiegel's *Progress in Neurology and Psychiatry* for 1946, in discussing abscess of the brain, state: "Conservative opinions agree, for the most part, that surgical drainage is essential despite the great value of chemotherapy." The same authors write no differently in 1947. Simple aspiration of a cerebellar abscess is recommended. In the 1946 *Year Book of Neurology and Psychiatry* the editor writes: "The radical method of extirpation introduced by C. Vincent has now, thanks to penicillin, become the method of choice in dealing with abscesses. Penicillin should never be depended on to sterilize an abscess. Pus should be evacuated and penicillin used to prevent the dissemination of the infection which has heretofore been feared."

From the Department of Neuropsychiatry, The Duluth Clinic, Duluth, Minnesota.

Presented before the Minnesota Society of Neurology and Psychiatry, September 13, 1947, St. Mary's Hospital, Duluth.

Case Report

The patient was a fourteen-year-old boy, who was admitted to St. Mary's Hospital in Duluth from a small town in Wisconsin on February 16, 1947. About four weeks before, he had had a drainage from both ears, which persisted for about ten days. Two weeks before admission, he developed a severe headache in the temporal and occipital regions. Vomiting and nausea had ensued, and there had been some epistaxis (a physician had been examining the nose). There had also been a tremor in the right hand and weakness in the right upper extremity. The father stated the patient had had penicillin injections, though he was not sure of the amount, but at least twenty-nine were given during the early stage of otitis. The right ear drained more profusely and for a longer period than the left. The mother, in a later interview, said the patient had had an apparent occasional involuntary movement of the

right hand in the spring of 1946. The patient only recalled that he had a "funny feeling" in the right shoulder and right hand for a short time in the early part of 1946.

The physical examination revealed nothing pertinent. An eye, ear, nose and throat department report indicated there was no evidence of an otitis media at this time and the eardrums were dry.

Neurological examination revealed the following: The patient was a well-nourished and well-developed teenaged boy, who was somewhat listless, though alert and co-operative to questions and directions. The recumbent position made him subjectively dizzy. There was no dysphasia. Slight stiffness of the neck was present, with a questionable Kernig's sign bilaterally. There was no tenderness over the scalp. Hearing was probably equal bilaterally. The fundi were normal except for a slight fullness of the inferior margins of both discs. The visual fields, to confrontation tests, were normal. The pupils were large but equal and reacted well to light. A horizontal nystagmus with gaze to the right, quick component to the right, and a less pronounced vertical nystagmus with upward gaze were present. (Later a slight nystagmus was also observed with gaze to the left.) Gaze to the right made the patient dizzy. The corneal reflexes were equal and the cranial nerves were otherwise intact. Slight weakness of the right upper extremity and pronounced intention tremor and adiadokokinesis were found in the right hand. There was no sensory loss to pinprick or cotton. A slight in-co-ordination of the right foot on heel to knee test was evident, and wiggling of the toes of the right foot was much slower than of the left. The tendon reflexes were considered normally active in the upper and lower extremities, though perhaps the right radial was less active than the left. The abdominals were active and equal in all four quadrants. There were no pathological reflexes, and no clonus was elicited. There may have been slightly less muscular tonus in the right upper extremity than the left. The gait and Romberg were not tested.

His temperature was normal on admission and remained thus. Laboratory reports were as follows: red blood cells 4,720,000; white blood cells 5,150 per c.c.; hemoglobin 14.1 grams and color index 1.03; Schilling —2 basophiles, 48 segmented cells, 49 lymphocytes and 2 monocytes. Urinalysis was essentially negative, except for 1 or 2 white cells. Blood culture was sterile at all times. Blood nonprotein nitrogen was 37 milligrams per cent. Sedimentation rate on February 16, 1947, was 11 mm., incomplete. Blood findings and urinalysis remained essentially normal throughout hospitalization. On February 21 the color index was reported as 0.95 with a 13.2 grams hemoglobin.

Roentgenograms of the mastoids were reported as follows: "No definite evidence of mastoiditis on either the right or left side. However, examination was incomplete, and the Law position should be made when the patient is able to co-operate."

The diagnosis was right cerebellar lobe abscess, secondary to otitis media.

Sulfadiazine and penicillin were started on the day of admission. The sulfadiazine level was brought up to 15 milligrams per cent, but the drug was discontinued after five days because of the patient's difficulty retaining it in his stomach. He received a total of 25 grams of sulfadiazine. Penicillin, 30,000 units every three hours intramuscularly, was given from the day of admission to the hospital, symptomatic treatment, including parenteral fluids, was also given. The patient's condition gradually improved, so that headache was present only intermittently and was not as severe as formerly, after he had been in St. Mary's Hospital about one week. He began to eat well, and the frequent emesis, present at first, became uncommon. The intention tremor of the right hand diminished considerably and the patient could finally touch the nose with the index finger of the right hand, which was impossible when he arrived at St. Mary's. The nystagmus diminished. Movement of the toes in the right foot improved considerably. The patient became more active and interested in his surroundings.

He was sent to the Mayo Clinic at Rochester on February 26, 1947, for consideration of operation.* By that date he had received a total of 2,160,000 units of penicillin intramuscularly in Duluth. Operation was withheld, and instead penicillin was continued in a dosage of 20,000 units intramuscularly every three hours until March 22, 1947. He received a total of 3,860,000 units of penicillin at Rochester and this plus what he was given in Duluth equalled 6,020,000 units. At Rochester, the patient appeared to make a complete recovery from what was also considered a cerebellar abscess, which was probably halted before it progressed beyond the early stages of inflammation.

The patient was seen in Duluth on August 14, 1947, and again on September 13, 1947, and the neurological examination was entirely negative each time. The patient looked well and had no complaints.

*Dr. H. L. Parker was his attending physician in Rochester.

COLD PREVENTION STUDY

(Continued from Page 505)

Summary

1. A controlled study indicates that influenza vaccine A and B is of no value for the prevention of the common cold.

2. The subjects who received influenza vaccine reported more reactions than the "control group," and the subjects who received vaccine made by one manufacturer reported more reactions than those who received vaccine made by another company.

This study was conducted at the request of the Commission on Influenza, Army Epidemiological Board, Office of the Surgeon General, U. S. Army, Washington, D. C.

A HISTORY OF MEDICINE IN SCOTT AND CARVER COUNTIES

(Continued from April issue)

Although the epidemic abated somewhat, more deaths occurred in the country during the next year, and several families at Jordan and Helena lost all their children. In December, 1882, diphtheria broke out in a malignant form in portions of Carver County. Ten or more children died within the first two weeks. The following May found several families afflicted at Jordan, one family having nine cases, and another family six. Eight patients died there before the second week of June. At Belle Plaine, diphtheria seemed to be on the increase, and complaints arose against the local board of health. In January, 1884, several cases appeared at Waconia, Carver County. January of the next year brought a number of cases and several deaths at Belle Plaine, and more complaints against the inactive board of health. Evidently no efficient measures could be evoked; one is led to believe that the condition was typical. In 1886 more than fifteen children died of diphtheria in Carver County, mainly in the smaller towns. Norwood, Young America, Dahlgren, Hollywood, and Watertown each lost at least one resident. At Waconia nine deaths among children were reported. It is probable that fewer than a third of the total number affected died.

During 1887, 1888, and 1889 diphtheria continued to take a small toll of children from each county. Characteristically, it flourished during the cold months. Large families had no effective way of isolating a sick child, so that two or three deaths frequently occurred in one household. Schools were closed at Camden, in 1887, and at Belle Plaine in 1888.

Certain homely treatments used for diphtheria were published in the county newspapers. "Fumes of turpentine thrown in a bowl of boiling hot water, and then cover the patient and bowl tightly in a heavy shawl" was suggested. If this failed, the recipe recommended sending for a physician.

During 1890 and 1891 diphtheria was considered epidemic at several points in Carver County, namely, Chaska, Waconia, Young America, Norwood, Camden, Benton, and Schnappsburg. The state board of health investigated the cases during December 1890. Dr. Grivelli was directed by the board to visit every school in the neighborhood and make a thorough examination of every pupil's throat. When a teacher at Camden objected to the examination, she was arrested by order of the state board of health. Under order of this board, physicians were employed to prevent the spread of diphtheria throughout the county. The towns had no provision for payments, so the bills were allowed from the county funds.

During January, 1891, the disease appeared in a fatal and highly contagious form at several towns in Scott County. Since November, 1890, there had been fifteen cases of diphtheria in the vicinity of Marystown, with eleven deaths. The disease spread to five families, and many more were exposed. Dr. J. B. Dunn was sent by the state board of health to investigate. Dr. C. N. Hewitt, secretary of the board, came at Dr. Dunn's request, and they conferred with the local boards of health in the infected districts.

Shakopee, surrounded by infected localities, forbade anyone to enter the city who "lived in a family infected with diphtheria or who attended church where any sick bodies were taken for burial or who in any way exposed himself to the contagion" until such a person had been thoroughly disinfected by a competent physician or local board of health and supplied with a certificate stating the time, place, and details of that procedure. The health officer, Dr. Dunn, effected the arrest of parties who failed to comply with the law. The *Shakopee Courier* announced that diphtheria had threatened to become epidemic in Scott County, but the prompt action of the state board of health helped to wipe it out. The statement was optimistic, perhaps untruthfully so, but at any rate diphtheria subsided in Scott County for the next three years.

Meanwhile, Chaska, lacking the equivalent of Shakopee's Dr. Dunn in the way of a health officer, experienced the most extensive scourge in years. The fall of 1892 saw sixty cases by the month of October. It spread alarmingly, unchecked by the authorities, and continued until the fall of the next year. One instance of carelessness may be cited as an example. A boy who had been very ill of the disease returned a book to the school library. Within a few days the child who had next handled the book had died. Apparently no effort was made to close the public schools that year.

In the years following, cases continued to break out from time to time. Nearly every town in the counties of Carver and Scott lost several children from diphtheria during the nineties. New Market Township in the southeast corner of Scott County counted thirty-two deaths during 1894-1896, many of them among adults. In 1894-1895 diphtheria was again epidemic at Shakopee. In January, 1897, thirteen deaths occurred from that disease in the towns of Jordan, Sand Creek, St. Benedict, and St. Lawrence. Schools were closed twice during the winter of 1895 at Hancock town. At this time, quarantine regulations were in effect in all the towns.

Generally speaking, more care was taken with diphtheria than with other diseases since it was considered the most dangerous. Diphtheria antitoxin came into general use about 1895, but it seemed to have no immediate effect in lessening the extent of the disease. Perhaps successful treatment resulted in less fear of the disease and more carelessness.

Of the other more dangerous contagious diseases, smallpox, scarlet fever, and typhoid fever, the first caused the most concern. Carver County seemed comparatively free from it, while in Scott County several towns were attacked. Many cases appeared at Jordan in 1881-1882, and in the eastern part of the county during July, 1882. Dr. James Dunn of Shakopee proved efficient on this occasion as on many others. Having found six children of Peter Saucer at Credit River ill of the disease, he sent his brother to Saint Paul to consult with the state board of health regarding a course to be pursued to prevent its spreading. Upon the return of his brother, Dr. Dunn, accompanied by a county commissioner, visited the locality and assisted the town supervisor in the organization of a town board of health and the establishment of quarantine regulations. Dr. Hewitt, secretary of the Minnesota State Board of Health, in company with Dr. Dunn, then visited the town authorities of Spring Lake, Cedar Lake, New Market and Credit River and succeeded in "awakening the necessary interest of the people and town officers to prevent its spreading." Dr. Dunn was appointed health officer for the four towns. One of Mr. Saucer's children, who died of the disease, had been sick a week, while the others attended school, and neighboring children and parents frequently visited the house. It was expected that the disease would spread in spite of precautions. In August Dr. Dunn reported, "There have been thirty-nine cases of smallpox in

six families; eight have died, others are convalescing, except three, who may be out of danger. Ten of the thirty-nine have been vaccinated; none of those ten have died, and only one was at all seriously ill, having been vaccinated years ago."

It is interesting to note that the county commissioners of Scott County petitioned the state legislature to make an appropriation to relieve the towns of Credit River and New Market from the pecuniary obligations which they, in good faith, assumed to prevent the spread of smallpox to the other parts of the state.

An incident occurred in April, 1900, which shows the dread of the disease which most of the people, including some physicians, had. Dr. Landenberger of New Prague heard of several cases of smallpox at Cedar Lake. He notified the board of health of Cedar Lake which, in turn, called upon him to investigate. Being ill, he sent Dr. McCarthy, who looked through the window at the patients and diagnosed the affliction as smallpox. McCarthy telegraphed the state board of health, and they sent Dr. William A. Hunt of Northfield to investigate. Seven cases were reported. Somewhat concerned, the local board of health then informed the state board of health, and that body sent Dr. J. B. Dunn of Shakopee. The latter made a thorough examination and reported that the patients were not suffering with smallpox but with some kind of pustulous disease of the skin.

Belle Plaine experienced a smallpox scare in August, 1894. A working girl had returned home from Saint Paul with what she thought to be chickenpox. As soon as it was diagnosed as smallpox, all at her house, and some who had just left, were vaccinated and quarantined. The girl was removed to a tent on the river bank where she was cared for by her mother and her step-father. The board of health acted promptly, effectively, and with unusual disregard for cost. The expenses involved about $300. Evidently so much had been done at the county's expense that the girl's parents expected to be paid for their services, their beer, and their fancy groceries. These bills appeared in the county records but, of course, were rejected.

Smallpox recurred throughout the state in 1899. All children had to be vaccinated before starting school that fall. No cases appeared in Scott or Carver Counties until the spring of 1900, when one case at Jordan caused the schools there to be closed. Several other cases occurred throughout Scott County that year. Actually, the smallpox cases in these counties were relatively few compared with those in other sections of the state, and also with cases of other contagious diseases within these counties.

Typhoid fever could hardly have been called epidemic at any time during the eighties and nineties. Scott and Carver Counties together averaged not more than three cases a year. At least one third of these cases, however, were fatal. In many instances, typhoid was contracted in Saint Paul or Minneapolis, and the patient returned to his home to be cared for.

Scarlet fever was prevalent at Shakopee in 1882 and 1886, and in a light form in the summer of 1889. It appeared again in the spring of 1895. No other towns in either county experienced so many cases. The total number could hardly have exceeded the number of typhoid cases, and the disease proved less fatal. Quarantine regulations probably did much to prevent its spread.

Measures were taken in the late nineties to make more explicit the duties of the town boards of health and to place the financial responsibility of their activities. In 1895 a law was passed in Carver County providing that "Each Town, Village and City shall provide for the payment of the expenses in their respective town, village, or city incurred by the control of contagious diseases." Heretofore, the towns frequently sought financial aid from the county or the state. In 1898 a state law required that every city should have a board of health to consist of not

less than three members, one of whom should be a physician, and that this physician should be the executive of the board. The terms of office and other details were specified.

Neither Carver nor Scott County could boast a hospital before 1900. Patients who could not be cared for at home went to Minneapolis or Saint Paul hospitals. It was customary for doctors in outlying towns to consult city physicians if a case proved difficult. Thus, people grew accustomed to looking to the Twin Cities for these services. It is probable that there was no adequately equipped operating room in either county until 1899, when the county physician of Scott County recommended the fitting out of such a room at the poorhouse for the use of the inmates. He was authorized to purchase the necessary furniture. At about the same time, Dr. S. N. Janes of Jordan ran a private hospital, probably very limited in size and equipment and supported for the most part by patients with chronic diseases. In 1900, Dr. M. Schober of Chaska, tried to interest the citizens in a project for the equipping of a first-class hospital in that city. He had succeeded in enlisting the co-operation of the Franciscan Brotherhood of the city and surrounding stations, and was at that time awaiting the sanction of Archbishop Ireland, of that diocese, to give his consent.

It is interesting to note that an unusually large quota of patients was sent from these two counties to the insane asylum at St. Peter. People who needed hospital care and who could not pay the price in the Twin Cities, sometimes managed to prove themselves eligible for state care and were admitted to the hospital at St. Peter. In the year 1899 six patients were sent there from Carver County alone. Knowing its value, Chaska had tried hard to get the fourth state insane asylum built there, but the institution was established at Anoka.

Medical societies flourished no better than hospitals in these counties. Contact with the Minnesota State Medical Society was established in 1869 with the election of Dr. John L. Wakefield, of Shakopee, as a member of that society. But this contact was neither close nor stimulating to most of the physicians in Scott and Carver Counties. Not more than eight or ten, altogether, became members before the turn of the century.

The Scott County Medical Society was organized about 1887 and continued for about three years. Its members were Drs. James B. Dunn, C. A. Entrup, A. B. Walter, M. H. Manson, G. R. Moloney, and J. F. Mulholland. No record of the society's aims remain, but a fee table used by them in general practice and surgery is in the possession of the Minnesota State Medical Association. The Scott and Carver County Medical Society, a more permanent institution, was organized in 1904. Many of the physicians now practicing in these counties have been active members of that organization.

Biographical Dictionary

Curtis B. Ames came to Chaska, Scott County, in April, 1866, to practice medicine. In 1869 he moved to Watertown, also in Carver County. Ames was very popular while in Watertown, having the political support of the Democrats there. In December, 1870, he was elected county physician at a salary of $450 a year. In the fall of 1872 he moved to Delano, Wright County, and a few months later he left with his family for Vicksburg, Mississippi.

C. B. Ames was the son of Dr. A. E. Ames, one of the oldest and first physicians of Minneapolis. He was reported to have been graduated from

one of the best medical institutions in the country, and also to have served in the Civil War.

F. M. Ball came to Carver, Carver County, in April, 1874. He remained only a short time, and in 1886 was established at Montrose, where he manufactured and sold a remedy for pulmonary diseases.

Charles Berry practiced medicine in Belle Plaine, Scott County, in 1866. He moved to New Ulm about 1870, where he was called by the Rev. Father Berghold to go in with him in building a hospital.

N. P. Birmingham was a physician who practiced in Belle Plaine, Scott County, in 1876 and a few years following. He succeeded Dr. Pashley after the latter's death.

F. J. Bohland practiced medicine in Belle Plaine, Scott County, in 1890 and for ten years or more after that. In 1896 he served as United States pension examining surgeon. He was county physician in 1879-1900, being assigned to that part of the county only. F. J. Bohland was born in Brooklyn, New York, on September 29, 1866. His early life was spent in Germany. When seventeen years of age, he came to Minnesota and completed his education at the state university.

John W. Bowers was graduated from the College of Physicians and Surgeons of Baltimore, Maryland, in 1882. He practiced in Chaska, Carver County, about 1887 and for two years or more thereafter.

F. W. Brett settled in Waconia, Carver County, in June, 1899. He was a graduate of Rush Medical College and served in various Chicago hospitals for a number of years. He held the position of surgeon for the Chicago and North Western Railroad at the time of his coming to Carver County. He was the son of Dr. C. Brett of Green Bay, Wisconsin.

W. P. Cash (or W. G. Cash) practiced in Norwood, Carver County, in 1878, and for nine years following. He served as county coroner in 1886. In February, 1887, he went to Louisville, Kentucky, for another course of study. In November of the same year he returned to Norwood. He became very ill and decided to move to Duluth.

Charles T. Chamberlain was graduated from the University of Michigan College of Medicine in 1884. In 1886 he was a resident of Belle Plaine, Scott County. Two or three years later he moved to Jordan and practiced there until his death in 1892.

P. L. Cormack opened an office in Jordan, Scott County, in September, 1878. In the following March he moved with his family to Dexter, Mower County, where he managed a drugstore in connection with the practice of medicine.

F. W. Cram came to Belle Plaine about 1878, and in 1879 moved to Jordan, where he became the co-partner of Dr. Walter. He was a graduate of Rush Medical College, and a very promising and popular young doctor. In October, 1880, he married Miss Dora Walter, the daughter of his partner, and in May, 1881, moved to Sheldon, Iowa, where he met with success.

Charles L. Davenport came to Shakopee in 1856 and formed a co-partnership with Dr. Weiser. He died in 1869 at Fort Adams, Mississipi, at the age of forty-five years.

S. B. Davis came to Carver, Carver County, in September, 1865, after having been for four years in the army as an assistant surgeon. About a year after his arrival he published in the Chaska newspaper a list of surgical operations performed by him in July, 1866. Eleven case histories were given, including the names of the patients, all of whom had recovered or were nearly well at the time of publication (August 11, 1866). He soon built up a large practice in Carver and the vicinity. In October, 1866, he received the commission of postmaster of Carver, but resigned a year later to go on a hunting excursion. He returned to Carver but remained only a short time.

Henry R. Diessner, a homeopathic physician, graduated from the Hahnemann Medical College, Chicago, in 1883. In January, 1884, he settled at Waconia, Carver County. His practice extended to Hamburg, Norwood, and Mayer. Dr. Diessner was one of the few homeopathic physicians in the county, and he had a good following of patients from the time of his arrival. In 1886, at the time of the diphtheria epidemic, he acted as health officer of Waconia. He was the most active Republican in the county. In 1897 he was elected a delegate-at-large from this state to the annual meeting of the Republican League Clubs convening at Detroit. The year following he was chairman of the Republican County Committee. He assumed control of the *Waconia Patriot,* the local paper, in 1899. At that time he was considered one of the most prominent citizens and businessmen in the county. During the years 1888 and 1894, he held the office of coroner for the county; also during the nineties he was postmaster at Waconia, chief of the Waconia fire department, secretary of the county Farmers' Alliance, on the United States examining board for pensions, and on the immigration committee for Carver County.

H. S. Donoho was graduated from the McDowell Medical College of St. Louis. He came to Chaska to practice in September, 1868. After remaining for two months, he moved to Rockford, Wright County, to associate himself with Dr. Richardson. The following April, he died of pulmonary consumption at the age of twenty-five years.

Dr. Dover came to Carver in 1867. The following statement was published at the time of his death in March, 1868:

> . . . Dr. Dover was a man of great intellect. He was without doubt one of the most thoroughly educated men in the State, and a good physician. But the Doctor was addicted to strong drink and it carried him away at last. . . .

James H. Dunn was born May 29, 1853, at Fort Wayne, Indiana. In 1854 the family located in Winona, and after the death of his father, in 1859, James H. Dunn was adopted in the family of Mr. Jesse Wheeler, of Winona County. At the death of Mr. Wheeler in 1868, Dunn entered the state normal school at Winona and by his own efforts supported himself until his gradution in 1871. He was at once employed as lecturer in the State Teachers Institute by the Hon. H. B. Wilson and later by Mr. Wilson's successor. During the intervals Dunn was principal of the Alexandria and South Center

schools, and completed a course in natural science at the University of Chicago. He then gave his whole time to the study of medicine, and in 1878, after a three years' course, he received the degree of doctor of medicine from the University of the City of New York, having spent a year of study at Bellevue Hospital and other hospitals in that city. In the fall of 1878 he was appointed instructor of natural sciences in the normal school at Mankato, which position he resigned in May, 1880, to enter upon the practice of his profession at Shakopee.

Dr. James H. Dunn was a skillful and successful surgeon and had a wide practice throughout the county. In 1882 he was given complete charge, as health officer, of the severe smallpox epidemic in the vicinity of Credit River and New Market. During the following year he took his brother, John B. Dunn, into partnership. In 1884 he traveled extensively in Europe, spending much of his time in study. In May of the year 1885 he moved to Minneapolis. He married Miss Agnes Macdonald of Shakopee in the fall of the same year. In Minneapolis he built up a large and successful practice, and became professor of surgery at the state university after the resignation of Dr. Charles A. Wheaton.

John B. Dunn was graduated from Rush Medical College in 1883 and entered into partnership with his brother, Dr. James H. Dunn of Shakopee, Scott County. Their card read:

Jas. H. Dunn Jno. B. Dunn
Dunn & Dunn
Physicians & Surgeons
Shakopee, Minnesota
Surgical and other important cases attended
at a distance by train or team.

The partnership continued until May, 1885, when Dr. James H. Dunn moved to Minneapolis and left Dr. J. B. Dunn in charge of the Shakopee practice. During his stay in Shakopee, Dr. J. B. Dunn acted as city health officer (1890-1892) and as county physician (1885, 1889, 1892 and 1894). He was a successful physician and very well liked in the community. He was anxious to practice in a larger place, however, and in 1887 he moved to West Saint Paul, a community of 20,000 persons, but after a trial of two months he returned again to Shakopee. During the winter of 1892-1893 he studied in Chicago. In February, 1893, he moved with his family to St. Cloud, Minnesota. He was a member of the Scott County Medical Society, which was organized about 1887, and a member of the Minnesota State Medical Society.

(To be continued in the June issue)

President's Letter

OVERTONES OF MEDICAL PRACTICE

Recently a well-known minister, addressing his congregation on what he termed the "overtones" of life, emphasized that there are many things in living besides the "meat and potato" existence. These overtones consist of the things which one does to make life more beautiful and just as in music the overtones lend color and appeal to the selection, so in daily life they contribute largely to the enjoyment of living.

A similar parallel is found in medicine. If a physician thinks of nothing but the daily routine of house calls, office practice, the operating room or the laboratory, he is soon in danger of losing the overtones which are so important to the successful practitioner. A good physician must embody more and must give more than just "meat and potato" medicine. He must on entering the sick room or the operating room infuse the patient with a sense of not only his skill but his human understanding. Look around you today and you will find those very qualities among the well-known professional leaders, which leads directly to the point I am trying to make—

Do medical conventions have a worthwhile purpose?

This question at some time or other is asked by every physician. Is it worth the effort to interrupt one's practice and incur the necessary expense and discomforts of travel? Every physician will agree to the importance of the aims of advancing scientific medicine and the wisdom of pooling his efforts with those of other physicians to extend medical service and advance medical standards. He will also acknowledge a purely selfish reason for going to a medical convention—that of self-improvement. I would venture to predict, therefore, that even the physician who possibly leaves a convention feeling he hasn't accomplished much, actually has made observations, contacts, discoveries of far greater value that he immediately realizes.

The broadening of the physician's practical knowledge through attendance at the scientific sessions; the stimulation and inspiration derived from reviewing the scientific exhibits; the exchange of helpful ideas with professional associates, both in meeting hall and in corridor; and the natural "lift" and enthusiasm which inevitably stem from the fellowship of such a gathering—all of these are powerful factors in creating those overtones which, if properly applied in everyday practice, serve commensurately to elevate the professional status of the physician, increase the service he is able to offer those in his community, and heighten both the regard in which he is held and the rewards which he may rightly expect for such service.

Annual conventions of the Minnesota State Medical Association have a reputation for consistently contributing in a broad way to these intangible but vital overtones of medical practice, and this year's meeting will be no exception. Since the entire program as planned by the Committee on Scientific Assembly, is printed elsewhere in this issue of the JOURNAL, I will not attempt to summarize it here. Certain highlights, however, are worthy of special attention.

As a unique departure from the scientific programs of former years, a series of Clinico-Pathological Conferences is planned for each morning during the general scientific assembly. Members of our own Association and authorities of other states will participate to provide an unparalleled opportunity for general discussion and instruction. Also, the public gathering on the last day, always an inspiring feature of our state meetings, will this year feature a panel of distinguished speakers exploring means of keeping the health of the people in Minnesota at a high level. Representatives of allied health organizations and other groups interested in health will be invited to attend this session.

The swiftly accelerating tempo of medical trends demands that every doctor make an earnest attempt to keep abreast of modern medical progress. Fortunately, members of the Minnesota State Medical Association have abundant and superior educational opportunities afforded them at the 1948 meeting, June 7 to 9, if they will but take advantage of them.

President, Minnesota State Medical Association

Editorial

Carl B. Drake, M.D., *Editor;* George Earl, M.D., Henry L. Ulrich, M.D., *Associate Editors*

THE STATE MEETING

THE program of the ninety-fifth annual session of the Minnesota State Medical Association appears elsewhere in this issue.

Simultaneously with the general scientific session, sessions will be conducted in the specialties, and an innovation this year will be the clinics in the various specialties to be held in several Minneapolis hospitals. Wednesday afternoon will feature the Public Health meeting, to which are invited all those interested in public health matters, such as social welfare workers, school and government authorities, and representatives of farm, labor, professional and civic groups. This meeting will be addressed by Dr. A. E. Cardle, president of the MSMA, Dr. John O. Christianson, superintendent of the University of Minnesota School of Agriculture, Lloyd E. Harris of Rochester, Senator Joseph H. Ball, Robert L. Novy, president of Michigan Medical Service, Inc., and Dr. Morris Fishbein. An attendance of some 1,500 is expected.

A social hour at the Hotel Radisson through the courtesy of Mr. George Ulmer, president of the Physicians and Hospital Supply Company of Minneapolis, will precede the annual banquet, also to be held at the Radisson Hotel. Addresses by President Cardle and Nicholas Amtoroff of New York will follow.

These are some of the highlights of the program. Those who attend will be able to make considerable selection in the way of clinics, round table discussion luncheons, scientific cinema, scientific and commercial displays. The distinguished guests from without the state always prove an attraction and the program lists a goodly number who will take part in the program this year.

Every member who can possibly absent himself from his practice, owes it to himself and his patients to take advantage of this opportunity.

DOCTORS AND THE PUBLIC SERVICE

THE U. S. Army needs more doctors. It now has some 1,200 regular army medical officers, approximately the same number it had at the beginning of World War II. It needs 3,000. Having a capacity of only 300 to 400 medical residencies in its army hospitals, the army has instituted a program to commission during the next two years some 600 residents and 600 interns in civilian hospitals and leave them in the civilian hospitals for their training on full army pay and allowances. One year of service for each year of training will be required of those commissioned during their hospital training, although the purpose of this step is the training of physicians for a medical career in the army as specialists and otherwise.

This plan is a special inducement to increase the medical personnel of the army but will take several years to develop the personnel needed. As everyone knows, legislation is being considered for the re-establishment of a Selective Service System and for the first time in our history for the inauguration of a National Service Training program. Included in the proposal are provisions for induction of doctors of medicine, dentistry and veterinary medicine under the age of forty-five "in accordance with such procedures as the President may prescribe." The registration and classification of doctors will doubtless provide for the allocation of the total medical means of the country in case of a great emergency. Presumably, those who received medical training at government expense and those under thirty-five who have had little or no service will be on the priority list.

As voluntary recruitment in the army has not been sufficient to maintain our army at a strength deemed necessary for national protection, a compulsory National Service Training program has been considered necessary. If enough medical men do not enlist to meet requirements, the drafting of doctors would seem the only logical step to take. Never in time of war has it been necessary to draft the medical profession. In peace-

time, there is not the same incentive of patriotism for physicians to enter the armed services. Assurance has been given that in case of another war, the regular army physicians and surgeons will not be delegated to administrative jobs but will rather continue their professional specialties. A career in the army thus should be more attractive to the scientifically inclined medical man.

The Veterans Administration is said to be having difficulty in obtaining sufficient medical personnel for their hospitals. Recourse has already been had to assigning regular army doctors to some of their hospitals. The attempt may be made to assign drafted medical men to the VA hospitals, which procedure is bound to meet with violent opposition. It is to be hoped that drafting of doctors for the army and navy will not be necessary, but drafting them for veterans' hospitals would be a definite example of governmental autocracy.

The medical profession agrees heartily that the veterans are entitled to the best of medical care for disabilities resulting from their service to their country. That large percentages of the inmates of veterans' hospitals are being treated for conditions unrelated to service is, and has been for years, a source of irritation to the medical profession.

According to present regulations, hospital beds in veterans' hospitals are allocated to veterans with non-service-connected ills when available. Possibly, the solution of the dilemma which seems to be confronting the Veterans Administration will be, of necessity, a more strict limitation of hospital beds to service-connected cases.

The private practice of medicine is facing a serious situation if, with the provision of additional veterans' hospitals and care being provided for some 8 million veterans for both service-connected and non-service-connected disabilities, this large block of the population is to be withdrawn from the private field. The situation will be even more serious if an attempt is made to include hospital care for the families of veterans. This would add some 50 million more to the number eligible for hospital care at government expense.

Of course, the lack of veterans' hospital facilities to care for the large number of veterans suffering from service-connected disabilities resulted in the happy solution whereby the services of private physicians were employed. This has been a source of some income to private physicians, particularly in the outpatient care of veterans suffering from service-connected disabilities. Outpatient care in the large centers of population being in large measure supplied by government-operated clinics, physicians outside the centers have profited more than those in the cities. It is said that the time consumed by veterans in attending the outpatient clinics operated by the Veterans Bureau has made them less popular than the services rendered for the Bureau by private physicians.

Every effort should be made to forestall the inclusion of the care of non-service-connected disabilities for veterans and their dependents even though the profession at large is used to supply that care. This would place the burden of the medical care of half the population of the country on the shoulders of the taxpayers.

MINNESOTA BLUE SHIELD PLAN

THIS issue contains on page 584 a communication from Mr. Arthur M. Calvin, Executive Secretary of the Minnesota Hospital Service Association, embodying the plan for the proposed Blue Cross—Blue Shield national association which evolved from the conference of representatives of national organizations held in Los Angeles on March 30, 1948.

As stated in an editorial entitled "Proposed Blue Cross-Blue Shield Merger," which appeared in our March issue, considerable opposition has been voiced to the plan of the merger as first proposed. A perusal of the new plan, as outlined in Mr. Calvin's communication, will show that the functions of the proposed national association of the two plans will be carried out by a Board of Governors and an Executive Committee equally representative of the Blue Cross and Blue Shield organizations and the American Hospital and American Medical Associations. It would seem, too, that ample provision will be made so that there will be no danger that the national association will encroach upon the autonomy of the state plans.

The new proposal that the national association of the Blue Cross and Blue Shield plans shall be an association of state plans, and not a large national insurance company, would seem to dispel the criticism that a large national insurance

company is to be formed in competition with private insurance companies. As a matter of fact, private insurance companies and medical associations have a common interest in providing hospital and medical insurance to meet the public demand and obviate the need of compulsory governmental insurance. While the non-profit hospital and medical plans sponsored by the hospital and medical associations have been showing satisfactory progress, the private insurance companies have also been markedly increasing their sale of policies. The medical profession wishes them the best of success, and we would go so far as to wish them godspeed, even if through better organization and insurance know-how they show themselves able to undersell our non-profit organizations. The important point is that hospital and medical insurance shall be widespread enough to meet the need.

At the inaugural dinner of the Minnesota Blue Shield Plan, which is Minnesota Medical Service, Inc., held at the Coffman Memorial Union at the University of Minnesota on April 13, several hundred interested guests heard a number of representatives of hospital, medical and nurses' organizations wish the Minnesota Blue Shield Plans success. The meeting was also addressed by the guest of honor, Dr. Paul R. Hawley, who is the present executive officer of the combined Blue Cross and Blue Shield commissions. Medical and hospital organizations can say "Amen" to the sentiments expressed by the former general.

METHIONINE IN THE TREATMENT OF CIRRHOSIS OF THE LIVER

THE frequent occurrence of cirrhosis of the liver in alcoholics has been explained as due not to the alcohol but to dietary deficiency. In the past, the treatment of cirrhosis has been on the whole futile.

Since attention was called to the value of methionine in the treatment of certain forms of hepatitis due to chemical poisoning, the hope has been expressed that this amino acid might be of some value in the treatment of cirrhosis of the liver. A recent editorial[1] in *The Journal of the American Medical Association* indicates that it has.

Beams and Endicott[2] have reported a short series of cases of cirrhosis in which liver biopsies were taken before and after treatment with high protein diet, crude liver injections and large doses of brewers' yeast—one series receiving 2 to 5 grams of methionine by mouth daily, and the other series not. While all the patients who received the methionine and some of those who did not receive it showed a favorable response, as indicated by histological changes in the liver, and while clinical improvement did not always correspond to improvement in the liver, methionine was given the credit for the better outcome in the patients treated.

In the nine patients who received the treatment supplemented with methionine, all showed histologic changes in the liver indicating a favorable response to the treatment. Five of them showed clinical improvement also, and three have remained well from one to two years. Two of the five patients ate poorly, continued to use liquor, and had recurrences after seven and twelve months, respectively.

The reported favorable results from the outlined treatment including methionine indicates further clinical trial.

1. Editorial. Hepatic Cirrhosis treated with methionine. J.A.M.A. 136:934, (April 3) 1948.
2. Beams, A. J. and Endicott, E. T.: Gastroenterology. 9:718, 1947.

MINNESOTA DEPARTMENT OF HEALTH

The Section of Medical Laboratories of the Minnesota Department of Health continues to offer microscopic, bacteriologic, and serologic examinations for all infectious communicable diseases, reports Dr. Paul Kabler, chief of that section. Recently, additional tests have been made available for virus and rickettsial diseases, primarily the encephalidites and pulmonary infections.

For best results in diagnostic tests for virus and rickettsial diseases, the laboratory requires a specimen collected during the acute phase of disease and another specimen collected during the convalescent stage, usually three to four weeks later. These two specimens are essential for comparative purposes, because it is the increase of antibody content during the intervening period that is of prime diagnostic significance. A full vial of blood should always be submitted for serologic tests.

"Submission of adequate specimens for laboratory diagnosis will greatly assist both the practicing physician and the Section of Medical Laboratories," says Dr. Kabler. "Physicians will receive better service if specimens sent to the laboratories are collected carefully, in adequate amounts, and mailed promptly, accompanied by the data card completely filled out with the test desired plainly stated. The chance for mis-diagnosis is augmented when specimens are collected too hastily or kept too long before they are mailed."

The laboratories of the State Department of Health constitute one of the oldest sections of the organization.

A laboratory was operated by Dr. Charles N. Hewitt, first state health officer, in the early days of the Health Department at Red Wing, Minnesota. In 1893, the laboratory work of the Board of Health was moved to the University Campus, and since that time the work has continued to be done there. However, the Health Department laboratories have no administrative connection with the University.

CANCER—A NEW MEDICAL JOURNAL

A new medical journal entitled *Cancer,* to be published by the American Cancer Society, will appear shortly. As the title intimates, the journal will be devoted to the subject of cancer from a surgical, medical, radiological, public health and educational standpoint and will publish original articles of high calibre only.

A long list of scientists representing clinical medicine and research makes up the Editorial Advisory Board, with Fred W. Stewart, M.D., acting as editor, Harry E. Ehrlich, M.D., assistant editor, and Douglas A. Sunderland, M.D., as abstract editor.

It is felt that although two important cancer journals now exist, they are largely devoted to reports of experimental laboratory research, and clinical papers are scattered among numberless other journals. *Cancer* will be devoted to the subject of cancer with major emphasis on clinical reports and experimental studies of particular value to those interested in the subject.

Original papers may be submitted to the editor, Dr. Fred W. Stewart, 444 East 68th Street, New York 21, New York.

WARNING—CUTTER LABORATORY INTRAVENOUS PREPARATIONS CONTAMINATED

In late April, hospitals were notified by the AMA to discontinue use of Intravenous solutions manufactured by Cutter Laboratories, Berkeley, California, because of contamination discovered in one batch of glucose solutions for intravenous use. Discovery of contamination in another and entirely different glucose solution, dextrose 10 per cent in Ringer's solution, has led the company to warn hospitals and physicians not to use any of the Cutter preparations intended for intravenous use until the thus far unsolved source of contamination has been found. Even the flasks made by the Cutter Laboratories should not be used. Products should be returned to the laboratory.

TUBERCULOSIS AND ERYTHEMA NODOSUM

Even if not more than two-thirds of the cases of erythema nodosum are associated with a tuberculous primary infection, it is obvious that every tuberculin-positive case must be treated in private practice as a possible expression of tuberculosis until thorough examination has shown that this possibility can be ruled out. The best guide to the etiological diagnosis seems to be the vesicular tuberculin reaction.—Hans Jacob Ustvedt, M.D., *Tubercle,* December, 1947.

In Memoriam

WARREN FETTERLY

Dr. Warren Fetterly of Minneapolis, formerly of Virginia, Minnesota, was found dead in his garage April 6, 1947. Death had been caused by carbon monoxide poisoning, presumably the day before.

Dr. Fetterly was born in Minneapolis, March 7, 1903. He obtained a B.S. degree from Hamline University in 1926 and an M.D. degree from the University of Minnesota in 1929. He interned at St. Mary's Hospital in Duluth and was associated with Dr. G. R. Dunn in Minneapolis seven years before joining the Malmstrom-Sarff Clinic in Virginia in 1937.

He is survived by his wife.

LEO A. HILGER

Dr. Leo A. Hilger, of Saint Paul, died December 30, 1947, after several weeks' illness.

Dr. Hilger was born in Pierre, South Dakota, on January 21, 1887, and came to Saint Paul in 1896. His early education was at Cretin High School and St. Thomas College, and he was graduated from Marquette Medical School in 1913.

He began practice in Saint Paul in 1914 after an internship in St. Joseph's Hospital. He was associated with his brother, Dr. Dave Hilger, and for many years worked with Dr. Fred Plondke at St. John's Hospital. He was Chief-of-Staff at St. Joseph's Hospital and for twenty-five years devoted his time and his excellent surgical knowledge caring for the indigent sick at the Ancker Hospital.

Dr. Hilger was a member of the Ramsey County Medical Society, Minnesota State Medical Association, American Medical Association, Saint Paul Surgical Society, a fellow of the American College of Surgeons, and Chief Surgeon of the Omaha Railway.

He is survived by his wife, Mary, three children and one sister and four brothers.

Edward C. Gibbs, M.D.

EDWARD H. NELSON

Dr. Edward H. Nelson of Chisholm, Minnesota, died at the Hibbing General Hospital on March 29, 1948, following a long illness.

Dr. Nelson was born in Minneapolis, March 30, 1875. He obtained his medical degree from Hamline Medical College in 1903 and interned at St. Barnabas Hospital in Minneapolis.

He joined the staff of Rood Hospital, now the Mesaba Clinic, on March 25, 1904. For the past eight years, he had been manager of the Mesaba Clinic.

Dr. Nelson served as mayor of Chisholm in 1910, 1911, 1918 and in 1929, and for twenty-one years was a member of the board of education at Chisholm.

He was a member of the Masonic Lodge and the Elks. In 1940, he was honored at a testimonial dinner

tendered by the Junior Chamber of Commerce of Chisholm.

He was a member of the St. Louis County Medical Society, the Minnesota State Medical Association, and American Medical Association.

On July 26, 1905, Dr. Nelson married Marie Saucier of Minneapolis.

He is survived by his wife and two daughters, Lucille Nelson of Minneapolis and Mrs. Irving Coryell of Chisholm, and a half brother, Dr. Kenneth R. Nelson of Boston.

LEO P. MOONEY

Dr. Leo P. Mooney, practicing physician of Graceville, Minnesota, since 1936, died of a heart attack on March 12, 1948. He had been ill two weeks.

Dr. Mooney was born at Madison, Minnesota, October 4, 1896. He obtained his medical education at the University of Minnesota, graduating in 1926. Following an internship at St. Mary's Hospital, Minneapolis, he practiced at Marble, Minnesota, from 1927 to 1936, when he moved to Graceville.

He was a member of the West Central Minnesota Medical Society, the Minnesota State Medical Association and American Medical Association.

HARRY OERTING

Dr. Harry Oerting was born in Saint Paul, Minnesota, in 1887. His preliminary education was completed in Saint Paul, and he received his Doctor of Medicine degree from Harvard University in 1917. He served as first lieutenant in World War I.

Dr. Oerting was very active in both medical and other scientific circles. He was a member and a former president of the Ramsey County Medical Society, a member of the Minnesota State Medical Association and the American Medical Association. He was also a member of the Central Society for Clinical Research. He was assistant clinical professor of medicine at the University of Minnesota, and he was certified by the American Board of Internal Medicine. He held memberships on the staffs of Ancker Hospital, the Charles T. Miller Hospital, St. Joseph's Hospital and St. Luke's Hospital. He was also a member of many lay organizations.

Dr. Oerting died after a brief illness on January 30, 1948, as a result of a coronary thrombosis. He is survived by his wife, Marie Johnson Oerting, and a daughter, Dorothy Oerting.

JOHN F. BRIGGS, M.D.

GEORGE BROSIUS WEISER

Dr. George B. Weiser, of New Ulm, died March 23, 1948, after an illness of several months. He was ninety years of age.

Dr. Weiser was born at Dalmatia, Pennsylvania, on September 7, 1857. He graduated from the Jefferson Medical College in 1897. He later took a supplementary course at the Philadelphia School of Anatomy and a special course in skin diseases under Professor J. V. Shoemaker in Philadelphia.

He began practice in McKees Half Falls, Pennsylvania, in March, 1879, but came to New Ulm in 1893. He had practiced over sixty years when he retired several years ago. Dr. Weiser had an active, long and useful life. He was a member of the board of education of New Ulm from 1898 to 1921 and president of the board for twenty years, a member of the first advisory commission of the Minnesota State Sanatorium for Tuberculosis, a member of the Minnesota State Board of Medical Examiners from 1917 to 1933, and twice president of the Board. He served as Associate Editor of MINNESOTA MEDICINE from 1918 to 1937. He was a member and former president of the Redwood-Brown Medical Society, and a member of the Minnesota State Medical Association and the American Medical Association. He was chairman of the Brown County Republican Committee from 1914 to 1932, a member of the Brown County Exemption board during World War I, and public school physician for many years. He was president of the Brown County Bank for a number of years, vice president of the Essig State Bank, director of the Citizens State Bank and the State Bond and Mortgage Company.

On October 2, 1890, Dr. Weiser was married to Sarah C. Schoch at Selingsgrove, Pennsylvania. Mrs. Weiser died on February 24, 1948. One daughter, Mrs. C. J. Ekelund of Pontiac, Michigan, and three granddaughters survive.

Several years ago, Dr. Weiser and Mr. Jacob Klossner, Jr., were honored by the members of Charity Lodge on the occasion of their fiftieth anniversary as members of the Masonic order. He took a great interest in the affairs of the local masonic fraternity and upon the fiftieth anniversary of the Charity Lodge, penned the history of the local fraternal group.

CLAUD WHITING WOODRUFF

Dr. C. W. Woodruff, practicing physician of Chatfield, Minnesota, for forty-three years, died March 24, 1948, at Pomona, California, after a long illness. He was seventy-one years old.

Dr. Woodruff was born at Elgin, Minnesota, October 17, 1876. After attending the University of Minnesota for three years, he graduated from Rush Medical College in 1901.

He practiced at St. James for a few months, then moved to Wykoff, Minnesota, and in 1905 came to Chatfield.

Dr. Woodruff served in the army medical corps during World War I and was chairman of the World War II Fillmore County draft board during its existence. He was an active member of the Olmsted-Dodge-Fillmore-Houston County Medical Society, the Minnesota State Medical Association and American Medical Association. He was also a member of the Masonic fraternity, including the Shrine, Knights Templar and Scottish Rites. He was also chairman of the Board of Trustees of the Chatfield Presbyterian Church for many years.

On October 29, 1902, Dr. Woodruff married Dora Dunn of Elgin. Mrs. Woodruff died on May 5, 1947, and a son, Paul, died in August, 1939. Surviving him is his daughter, Helen, who was with him in California when he died.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics

Minnesota State Medical Association
George Earl, M.D., Chairman

IMPARTIAL AGENCY VETOES COMPULSORY HEALTH INSURANCE

A significant statement on medical care for the individual prepared by the Brookings Institution of Washington, D. C., an impartial agency, has been released. It points out quite objectively certain defects in the compulsory system now being proposed for our national health program.

It would seem unwise at this time, the Brookings Institution concludes, to substitute by national law for the present system, a system of compulsory health insurance which would have the "unfortunate tendency to freeze policies and eventually retard medical progress."

The statement follows a study of the national health picture made at the request of Senator H. Alexander Smith of New Jersey, who, in his position as chairman of the subcommittee on health of the Senate Committee on Labor and Public Welfare, has been investigating proposed federal health legislation.

Particularly under scrutiny have been S. 1320 (successor to the Wagner-Murray-Dingell bill of 1946) and S. 545, the Taft-Smith-Ball-Donnell bill.

Present System Basically Sound

That the present system of providing health care is basically sound is one of the most important conclusions drawn in the Brookings report. Proceeding from that point it discusses objectively some of the weak points and flaws that exist and suggests possible corrective measures; compulsory health insurance as a solution is flatly vetoed.

The medical profession has always maintained that no other nation in the world has better health than that enjoyed in the United States and that a system of medical service with that kind of record should not be scrapped. This point is emphasized in the Brookings report.

The report compares health in the United States with that of other countries—as their health conditions existed before being thrown off base by the war—and concludes that "no great nation in the world has among its white population better health than prevails in the United States. A few small homogeneous countries such as New Zealand with respect to its white population are slightly ahead of the United States as a whole, but certain states of the United States with larger populations equal them."

A greater progress in the application of medical and sanitary science than any other country is also noted. Reference is made to low mortality and morbidity rates for the infectious diseases and an increase in life expectancy, and it is shown that this general trend toward improvement is apparently going to continue.

Draft Statistics No Argument

Considering the ferment over the rate at which young men were rejected from the draft and the way the figures have been used to show evidence of failing American health, it is interesting that the Brookings report declares that "the so-called draft statistics are unreliable as a measure of health of the nation and cannot be used to show the extent of the medical needs of the country as a whole."

No argument to support this contention has been released at this time. The present report is a preliminary to a more detailed one to be presented later and to include discussion and data upon which the conclusions are based. In preparing the report, Drs. Lewis Meriam and George W. Bachman, two of the Institution's senior staff members, both of whom are familiar with government service, medical research and public health, analyzed the major issues involved in the question of changing the present system through examining extensively the literature in the field. They also examined statistics, government administrative policies and procedures, population trends and social and economic problems related

to health and drew upon experience in administration and research in the field of public health, disease control and medical relief. No attempt, however, is made to deal with strictly medical problems.

Suggest Different Approach

The Brookings Institution report attacks some of the solutions being advanced for present health problems. For example, the subsidy for areas which cannot support adequate public services, the report says, will not do the job. This problem of providing health work, education, highways, etc., for extremely poor rural areas with little or no resources must be handled with an entirely different approach, perhaps importing newer or better economic activities or moving the people to areas less bleak and less expensive to administer. As for health insurance, compulsion won't do either, the report shows. *People won't be any more able to pay a health tax if it is forced upon them than they would be ordinarily able to budget for medical bills on a voluntary basis.* The alternative for those who *can* pay is to let them decide for themselves how much health care they are willing to pay for and then to take out insurance if they so desire. For those unable to pay, no matter what system is used, provision will still have to be made for them through public funds or charity, it is pointed out.

Other arguments against compulsion are advanced. It is shown that compulsory health insurance would mean tight government control over people and agencies in medical and health work. This field would be harder to manage than any other yet entered by the government, requiring thousands of employes. Such control would tend to discourage initiative and development. Then the whole question of the difficulty of eliminating politics comes in, as does the danger of government interference threatening the doctor-patient relationship, which would ultimately affect the quality of medical service. Costs of medical care would skyrocket to make up for the administrative burden. What it boils down to is that the people will be paying *more* for an *inferior* product.

Compulsion Won't Meet Demand

Compulsory health insurance is not going to create services where none exist, nor will it stretch facilities, the report points out. There are not enough facilities or trained workers—doctors, nurses, dentists—to meet the demand for service that a national program of the type proposed would stimulate.

Methods of paying physicians under such a plan were also studied by the Institution. Of the three known methods—fee for service, per capita and salary, none can be fitted into the system without socializing the profession. Fee for service would be least likely to shackle the profession, but it would be difficult to administer. Difficult to handle also would be the per capita system, which calls for a higher degree of socialization. Almost complete socialization, the report says, would come from the salary system.

Could a country once committed to compulsory health insurance turn back if headed for the rocks? Wouldn't it rather have to patch up defects with even more rigid federal control and administration? These questions are left to the health insurance advocates by the Brookings Institution. The report doesn't ask that they be put to a test; results might be disastrous. Instead it makes a series of recommendations—(1) Leave it up to the individual states to decide whether compulsory health insurance should be adopted or the health professions should remain free; (2) Devote resources and energies of the federal government to research in public health, health education at school level, teaching preventive medicine, assisting in providing physical facilities and training personnel and caring for indigents; (3) Leave adult education campaigns for control and prevention of disease to national, state and local voluntary organizations. It must be remembered, the report emphasizes, that *good health is not exclusively a matter of medical care.*

Governors Oppose Compulsion

In his attempts to get at the current opinions from persons other than those connected with health on national health legislation, Senator Smith not only called in the Brookings experts, but he also put the question to the governors of the forty-eight states. Results should be heartening to physicians—not a single governor favored federalizing medicine.

Senator Smith outlined the two proposals now before Congress, S. 1320 and S. 545. Of the thirty-nine governors reporting, all of them turned thumbs down on S. 1320 which calls for payroll taxes and other taxes to pay for an over-all medi-

cal program by the government. S. 545, which would allot federal grants to states in order that they might develop their own programs was approved by twenty-five of the governors. Five did not like either measure; eight indicated no preference. Nine governors did not reply.

BRITISH DOCTORS PROTEST INCREASED SOCIALIZATION

Attempts by the British Labor Government to push through a program of increased state control over medicine has met with severe opposition. British doctors have voted to boycott the universal free medical service plan, scheduled to take effect July 5, 1948.

What the British Medical Association objects to most are the features which make the physicians salaried servants of the state; take away their rights to choose the form, place and type of work they prefer; and do not give the medical profession adequate representation in the administration of the program.

The program was worked out according to principles laid down by Sir William Beveridge and will be directed by Minister of Health Aneurin Bevan. Not only was the British medical profession not consulted in the development of details, but on the eve of the plebiscite held by the doctors to determine whether they would participate, Mr. Bevan charged the British Medical Association with conspiracy and sabotage.

Conflicts with Standards

The new national health service plan conflicts with the traditions and standards of medicine, said the doctors as they voted against it 24,340 to 4,084. Furthermore, they maintain that they have been heretofore servants of their patients and do not wish to take on the additional burden of serving a top-heavy state plan.

"Public safety demands that the individual doctor shall be free to certify what he finds in his patient without fear of government influence." This statement was made by the Council of the British Association; it reflects the majority opinion of all British doctors.

The present move to nationalize medicine in Britain is not a sudden development. It has been on the way since 1942. Final enactment is due to the efforts of the present labor regime. The plan includes nationalization of all hospitals; doctors will be compelled to get government approval to hospitalize patients. The state will dole out all supplies, drugs and equipment. The pattern of socialism is followed through once more—the tendency it has to expand controls until the entire system is taken over.

WORLD HEALTH ORGANIZATION FAILS TO GET U. S. SUPPORT

With the blessing of the American Medical Association, the American Public Health Association, and practically every public health organization in the United States, the World Health Organization was born in New York City in July, 1946. This great charter for world health has been bypassed by the United States.

The Senate passed the bill to make the United States a member, but for some reason the House of Representatives tabled a bill to aid in establishing the WHO. The United States has taken the lead in supporting world-wide efforts at disease control, preventive medicine, nutrition, research, sanitation, housing. It seems strange that our lawmakers would thus neglect or ignore these very aims.

At the time of its founding, those who worked out the plans believed that the world was never more in need of a World Health Organization. The objectives were to secure the highest possible level of health for all people, to help the world back to health and sanity. It was hoped sincerely that these aims would be accomplisheed. Yet, how can they be accomplished without the support of this country?

The Medical Society of the State of New York has sent to Washington a resolution summarizing the need for an agency to promote health and to urge immediate rescinding of the action by the House of Representatives so that the United States can assume its proper role in assisting international co-operation for health.

O'BRIEN MEMORIAL PROFESSORSHIP

The Minnesota Division of the American Cancer Society at its April meeting established a full professorship in cancer research at the University of Minnesota, dedicated to the memory of Dr. William A. O'Brien, who was president of the division for ten years before his death. A $5,000 fellowship which was established by the division three years ago, and which is held at present by Dr. Robert A. Huseby, will be extended to the full professorship.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Saint Paul, Minnesota

Two Women Plead Guilty to Abortion Charge

Re State of Minnesota vs. Alma D. Peterson and Laura M. Finn.

On April 12, 1948, Alma D. Peterson, fifty-eight years of age, 6 Spruce Place, Minneapolis, entered a plea of guilty to an information charging her with the crime of abortion. On the same date, Mrs. Peterson also pleaded guilty to an information charging her with two prior convictions. Following a statement of the facts to the Court, Mrs. Peterson was sentenced to serve one year in the Minneapolis Women's Detention Home. Judge Hall told Mrs. Peterson that she would have to serve the entire year and that her sentence would not be shortened by the Court.

Mrs. Peterson and the defendant, Laura M. Finn, forty-five years of age, 9 South Ninth Street, Minneapolis, were arrested on March 10, 1948, by Minneapolis police officers following the hospitalization of a twenty-four-year-old unmarried Minneapolis woman. The patient was suffering from the after effects of a criminal abortion. The case was promptly reported to the Minnesota State Board of Medical Examiners, and the subsequent investigation resulted in the arrest of both defendants. The patient stated that she had contacted the defendant Finn, who, in turn, arranged to have the defendant Peterson actually perform the abortion. The abortion was performed by means of a catheter, and the sum of $100 was paid to the defendant Finn. Mrs. Finn retained $70.00 and gave the defendant Peterson $30.00 for doing the abortion.

The defendant Finn entered a plea of guilty on March 22, 1948, to an information charging her with the crime of abortion. Because of the fact that Mrs. Finn had a good record prior to her arrest, she was sentenced to a term of not to exceed two years in the Women's Reformatory at Shakopee by the Hon. Levi M. Hall, Judge of the District Court, and placed on probation for two years. The case against Mrs. Peterson was continued to April 12, on which date it was disposed of as stated above. The Court refused to place the defendant Peterson on probation for the reason that Mrs. Peterson was convicted of criminal abortion in the District Court of Hennepin County, on December 8, 1934, and again on February 7, 1944. In each of the prior cases, Mrs. Peterson was placed on probation. Neither of the defendants has any medical training.

CHRISTIAN MEDICAL SOCIETY

The annual convention of the Christian Medical Society will be held on June 25 and 26 in the Illini Building, 715 South Wood Street, Chicago, Illinois. An organization of physicians and medical students, the society recognizes no denominational barriers. With a membership exceeding 500, the organization has student members on more than thirty medical campuses and active groups on more than half of those campuses.

Reports and Announcements

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The American Congress of Physical Medicine will hold its twenty-sixth annual scientific and clinical session September 7, 8, 9, 10 and 11, inclusive, at the Hotel Statler, Washington. D. C. Scientific and clinical sessions will be given the days of September 7, 8, 9, 10 and 11. All sessions will be open to members of the medical profession in good standing with the American Medical Association.

In addition to the scientific sessions, the annual instruction courses will be held September 7, 8, 9 and 10. These courses will be offered in two groups. One set of ten lectures will be based primarily on physics and physiology, and attendance will be limited to physicians. One set of ten lectures will be more general in character and will be open to physicians as well as to physical therapists. The physical therapists must be registered with the American Registry of Physical Therapy Technicians. Full information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

CHICAGO MEDICAL SOCIETY POSTGRADUATE COURSES

Two postgraduate courses will be offered to physicians of the country in September by the Chicago Medical Society. The first course, Hematology and Neurology, will be given September 13 to 18, and the second, Cardiovascular and Respiratory Diseases, will be held September 20 to 25.

Sessions will be held in Thorne Hall on the Northwestern University Medical School campus. The faculty for the courses will be comprised of an outstanding group of teachers from all sections of the United States.

Further information may be secured from the Chairman, Committee on Postgraduate Medical Education, Chicago Medical Society, 30 North Michigan Avenue, Chicago 2, Illinois.

FREEBORN COUNTY SOCIETY

Tuberculosis was the subject for discussion at a meeting of the Freeborn County Medical Society in Albert Lea on March 18. Dr. Karl Pfuetze, of Mineral Springs Sanatorium at Cannon Falls, as the principal speaker, discussed results of x-ray surveys carried out last fall and reviewed the use of streptomycin in the treatment of tuberculosis.

Guests at the dinner included Dr. Henri Duloud of France and Dr. Chih Li Chu of China, both of whom are engaged in special work at the Cannon Falls sanatorium.

MINNESOTA STATE MEDICAL ASSOCIATION

Ninety-Fifth Annual Session

Minneapolis Auditorium, Minneapolis, Minnesota
June 7, 8, and 9, 1948

ANNOUNCEMENTS

Sectional Program—This year's program is again divided into two sections to be conducted simultaneously. The general scientific assembly will convene each day in the ground floor lecture hall to the left of the exhibit hall. Section meetings will be held on the mezzanine floor off the main corridor leading to the lecture hall.

Scientific Cinema—Scientific motion pictures will be shown in a room to the right of the exhibition hall before each morning and afternoon session, at the conclusion of the Monday and Tuesday sessions, and at each intermission. Provided by the Medical Film Guild, which has produced several research projects this year, each film represents a postgraduate course in the specialty covered. Of note is "Management of the Failing Heart," "A Clinic on Deafness," "Arterial Blood Pressure—the Instruments, Technique and Physiology," "Hypothyroidism," and many others. These films are available to the local medical societies at no charge; costs are defrayed by grants for postgraduate instruction. Projection service is also included at no charge.

Round Table Luncheons—A series of twenty-one Round Table Discussion Luncheons has been arranged for this meeting at Hotel Radisson. A set of ten luncheons will be held on Tuesday and ten on Wednesday; one luncheon is scheduled for Monday. Tickets may be purchased in advance for these luncheons, all of which are held at 12:15 p.m. Lists of subjects and leaders are printed in the program and on the reservation cards mailed with the program. Attendance at each luncheon is limited to *thirty;* late comers are accommodated according to their choice if limits have not already been reached. Tickets $2.00, tips included.

Public Health Meeting—A special conference entitled "An Unfinished Job" will conclude the convention program on Wednesday afternoon, June 9. Distinguished guest speakers will present a thorough and frank discussion of health needs, showing medicine's part and the interplay of other factors influencing health and welfare. Invited will be members of allied health organizations, social welfare workers, school and government authorities and representatives from farm, labor, professional and civic groups.

Medal—The Southern Minnesota Medical Association will again award a medal to the individual physician presenting the outstanding scientific exhibit. The award will be made at the banquet Tuesday evening, June 8, at Hotel Radisson.

Fifty Club—Tribute will be paid to members who this year have completed fifty years of practice in Minnesota by election to Minnesota's "Fifty Club." Candidates will be honored at the Banquet Tuesday evening and will be presented with lapel buttons and certificates at that time.

Technical Exhibits—A large and varied array of technical exhibits will be on display in the Exhibition Hall of the Minneapolis Auditorium. Every convention visitor will want to visit the booths for the opportunity, which they provide, of looking over what's new in the line of physicians' supplies and equipment, pharmaceuticals, medical books, et cetera; also, the revenue from sale of exhibit space makes possible the high quality of scientific program which characterizes our Minnesota meetings.

Woman's Auxiliary—Physicians' wives attending the meeting may secure programs for the business and social sessions of the Woman's Auxiliary at the Women's Registration Desk on the mezzanine floor of Hotel Radisson. All visiting women are cordially invited to attend the special events arranged by the hostesses of the Hennepin County Medical Auxiliary. Among these is a tea Monday afternoon at the Women's Club of Minneapolis, 410 Oak Grove Street, and the Annual Meeting and Luncheon at 10 a.m. and 1 p.m., respectively, at Hotel Curtis. Visiting women may attend the Breakfast at 10 a.m. Wednesday, June 9, in the Medical Arts Lounge.

SPECIAL SESSIONS

In addition to the general sessions to be held on Monday, Tuesday and Wednesday in the general lecture hall on the ground floor to the left of the exhibition hall, there will be five special section meetings in the mezzanine lecture hall. These will be held during the morning of each of the three convention days and Monday and Tuesday afternoons. Intermission periods will be observed from 10:15 to 11 a.m. and again from 3:15 to 4 p.m. at each session so that those who attend may visit exhibits, demonstrations and the scientific cinema.

Monday, June 7

9 a.m.—Symposium on Surgery of Emergencies (Orthopedic and Fracture Surgery)

2 p.m.—American College of Chest Physicians, North Midwest Chapter

Tuesday, June 8

9 a.m.—Symposium on Research Problems

2 p.m.—Minnesota Academy of Ophthalmology and Otolaryngogoly

Wednesday, June 9

11 a.m.—Minnesota Heart Association

CLINICS

A special feature at this meeting is a series of clinics at several Minneapolis hospitals, conducted by staff members, arranged for Tuesday and Wednesday. *Admission will be by ticket only; free tickets procurable at the Registration Desk, Auditorium.*

Tuesday, June 8

St. Barnabas Hospital—920 South 7th Street

8 a.m.—A Demonstration of Pre- and Post-Operative Parenteral Nutrition in Surgical Patients, Carl O. Rice, *et al.*

9 a.m.—A Demonstration of Caudal Anesthesia in the Obstetric Patient, John T. Moehn and O. F. Robbins

10 a.m.—A Demonstration of a New Principle in the Management of Heart Disease, Arthur Kerkhof, *et al.*

Asbury Hospital—916 East 15th Street

8 a.m. to Noon
- —A Demonstration of Varicose Vein Ligation, H. O. McPheeters, *et al.*
- —Gall Bladder Surgery, Henry Hoffert
- —General Surgery, Stanley Maxeiner, *et al.*
- —Fluorescein Visualization of Peripheral Vascular Circulation, H. A. Alexander

Wednesday, June 9

Abbott Hospital—110 East 18th Street

8 to 11 a.m.—Rectal Operations, W. A. Fansler, J. K. Anderson, *et al.*

Northwestern Hospital—810 East 27th Street.

9 a.m.—Pediatric Techniques, E. S. Platou, *et al.*

10 a.m.—Clinical Conference, Medical Staff, J. C. Miller, *et al.*

Veterans Hospital—54th Street and 48th Avenue South (Fort Snelling)

9:30 to 11 a.m.—Neurological Rehabilitation, Andrew J. Leemhuis and Louis C. Jenson, Building 55, Station 50 (Fort Snelling)

2 to 3 p.m.—Peripheral Vascular Diseases, Frank W. Quattlebaum, Conference Room, Building I (Veterans Hospital)

MOVIES

A series of special movies will be shown, by arrangement with the Local Committee, at various times during the convention at the Auditorium in Booth S-26.

Alimentary Diverticula—Horace G. Scott, Minneapolis

Facia Transplant Hernia Repair—Hamline A. N. Mattson, Minneapolis

Lumbar Ureterotomy for Stone—Frederick E. B. Foley, St. Paul

Progress of Patients with Poliomyelitis, Treated from 1946—Frederick J. Kottke, *et al,* Department of Physiology, University of Minnesota

Thyroidectomy—Martin Nordland, Minneapolis

Tourniquet Amputations—Stanley R. Maxeiner and C. D. Adkins, Minneapolis

Vein Ligations—H. O. McPheeters, Minneapolis

DEMONSTRATIONS

There will be a series of five obstetric manikin demonstrations arranged by the Committee on Maternal Health under the auspices of the Minnesota State Department of Health. Three of these will be presented at Round Table Luncheons, at 12:15 p.m. Monday, Tuesday and Wednesday, Hotel Radisson; the other two will be presented at 5:15 p.m. Monday and Tuesday in the Lecture Hall on the Mezzanine Floor at the Minneapolis Auditorium.

The first manikin demonstration will be given at 12:15 p.m., Admiral Room, Hotel Radisson, by Harold L. Gainey, Assistant Professor of Obstetrics and Gynecology, University of Kansas School of Medicine, Kansas City, who will repeat the demonstration at 5:15 p.m. that same day at the Auditorium.

On Tuesday, June 8, the demonstrator will be Earl C. Sage, Professor of Obstetrics and Gynecology, University of Nebraska School of Medicine, Omaha; the first demonstration to be given at 12:15 p.m. Admiral Room, Hotel Radisson, and again at 5:15 p.m. at the Auditorium.

John E. Faber, Department of Obstetrics and Gynecology, Mayo Clinic, Rochester, will perform the final demonstration at 12:15 p.m., Spanish Room, Hotel Radisson, Wednesday, June 9.

GUEST SPEAKERS

We are indebted to the following societies and organizations for guest speakers at this meeting:

The Minnesota Academy of Ophthalmology and Otolaryngology—Speaker, Dean McAllister Lierle, Professor of Otolaryngology, State University of Iowa College of Medicine, Iowa City.

The Minnesota Department of Health—Obstetric manikin demonstrators, Earl C. Sage, Professor of Obstetrics and Gynecology, University of Nebraska School of Medicine, Omaha; and Harold L. Gainey, Assistant Professor, Obstetrics and Gynecology, University of Kansas School of Medicine, Kansas City.

Minnesota Medical Service, Inc.—Speaker, Robert L. Novy, President, Michigan Medical Service, Inc., Detroit.

The Minnesota Radiological Society—Speaker, Paul Chesley Hodges, Professor of Radiology, University of Chicago, who will deliver the annual Russell D. Carman Memorial Lecture in Radiology.

The Minnesota Society of Clinical Pathologists—Speaker, Benjamin J. Clawson, Professor of Pathology, University of Minnesota, who will present the annual Arthur H. Sanford Lecture in Pathology.

The Northern Minnesota Medical Association—Speaker, Michael L. Mason, Associate Professor of Surgery, Northwestern University Medical School, Chicago.

The Northwest Pediatrics Society—Speaker, Russell J. Blattner, Professor of Pediatrics, Baylor University College of Medicine, Houston, Texas.

Other visiting speakers at this meeting:

The Honorable Joseph H. Ball, Senator from Minnesota, Washington, D. C.

John O. Christianson, D.Sc., Superintendent, University of Minnesota School of Agriculture, St. Paul.

Morris Fishbein, Editor, *Journal of the American Medical Association,* Chicago.

Erle Henriksen, Associate Professor of Gynecology and Consulting Pathologist, University of Southern California, Los Angeles.

Walter G. Maddock, Northwestern University Medical School, Chicago.

Ovid Otto Meyer, Chairman, Department of Medicine, University of Wisconsin, Madison.

GOLF

The Annual Golf Tournament of the Minnesota State Medical Association will be held at the Interlachen Country Club, Minneapolis, with tee-offs at 11 a.m. and 2:30 p.m. Details are being arranged by a committee, chairman of which is Dr. L. O. Doyle, Minneapolis. All medical golfers are being invited to enter and compete for the attractive prizes that have been donated.

HOBBY SHOW

The Physicians' First Annual Hobby Show will be held at the Minneapolis Auditorium all during the convention. A wide variety of interesting articles—representing the avocations of Minnesota doctors—will be on display: samples of wood carving, basket weaving, etchings, sketches and collections of everything from stamps to buttons. All Minnesota physicians may participate. L. G. Idstrom, Minneapolis, is chairman of the committee in charge.

SOCIAL EVENTS

Annual Banquet—The annual dinner for members, guests and their wives will be held at 7. p.m. Tuesday, June 8, in the Ballroom of Hotel Radisson. Nicholas Amtoroff, distinguished Russian physician, author and lecturer, and A. E. Cardle, Minneapolis, President of the Minnesota State Medical Association, will be banquet speakers. Tickets $4.00.

Preceding the Banquet there will be a social hour, from 5 to 6:30 p.m. on Tuesday, June 8, in the Italian Room, Hotel Radisson, arranged by the Entertainment Committee of the Hennepin County Medical Society and Mr. George Ulmer, President, Physicians and Hospitals Supply Company and the Ulmer Pharmacal Company of Minneapolis.

"A Midsummer Dream"—At 8 p.m. Monday, June 7 in the Ballroom of Hotel Radisson, the Dayton Company of Minneapolis, by arrangement with the Hennepin County Medical Society, will present a revue of fashions for summer, 1948, with a background of music. This will be followed by an evening of dancing. Music will be provided by Fred Oldre and his orchestra.

American College of Chest Physicians, North Midwest Chapter, Luncheon—At Noon Monday, June 7, Room 118, Hotel Radisson, chest physicians will hold a luncheon meeting. Reservations should be made in advance with S. S. Cohen, Oak Terrace.

Medical Women's Luncheon—The American Medical Women's Association, Minnesota Branch, will hold a luncheon meeting at the Curtis Hotel, 12:30 p.m. Monday, June 7, to which all women physicians are cordially invited. For reservations communicate with Nora Winther, 512 Medical Arts Building, Minneapolis.

Medical Veterans of World War II will meet at a luncheon at 12:30 p.m. Monday, June 7, at Hotel Radisson. Charles H. Mead, Jr., 815 Fidelity Building, Duluth, is in charge of advance reservations.

Minneapolis General Hospital Surgical Residents Society will hold their annual dinner for members and wives in the Admiral Room of Hotel Radisson, at 6 p.m. Monday, June 7. Advance reservations are to be made with Albert T. Hays, 1149 Medical Arts Building, Minneapolis, MAin 7458.

The Minnesota Society of Clinical Pathologists will hold a luncheon meeting 1 p.m. Wednesday, June 9, at the Leamington Hotel. For reservations contact Kano Ikeda, Miller Hospital, St. Paul.

Nu Sigma Nu Annual Get-Together—There will be a reunion of members of the Nu Sigma Nu Medical Fraternity at the Minneapolis Club for cocktails, dinner, and a social evening, on Monday, June 7, beginning at 5:30 p.m. Notify Charles N. Hensel, 613 Lowry Medical Arts Building, St. Paul, if you plan to attend.

Phi Beta Pi Medical Fraternity—All Phi Bets from every chapter are invited to a luncheon meeting at 12:30 p.m. Tuesday, June 8, at the Curtis Hotel. Plans will be announced later and tickets will be on sale at the Registration desk at the Auditorium. Arrangements are being made by J. K. Anderson, 1829 Medical Arts Building, Minneapolis, and F. F. Wipperman, 1921 Medical Arts Building, Minneapolis.

COMMITTEE ON SCIENTIFIC ASSEMBLY

Members of the Committee on Scientific Assembly who have worked diligently in preparing this year's program are:

A. E. Cardle, M.D., Minneapolis, *General Chairman,* L. A. Buie, M.D., Rochester, and R. R. Rosell, Saint Paul.

Section on Medicine—S. H. Boyer, Jr., M.D., Duluth, and R. V. Sherman, M.D., Red Wing.

Section on Specialties—Francis W. Lynch, M.D., Saint Paul, and C. J. Ehrenberg, M.D., Minneapolis.

Section on Surgery—J. T. Priestley, M.D., Rochester, and D. A. MacDonald, M.D., Minneapolis.

Local Arrangements—Charles E. Proshek, M.D., Minneapolis.

SCIENTIFIC PROGRAM

Monday, June 7

SECTION I—GENERAL SESSION

A.M.

8:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

9:00 *Clinical-Pathological Conference*.....General Lecture Hall
Subject: CARDIOVASCULAR-RENAL DISEASES
Presentation of Cases—Elexious T. Bell, Minneapolis
Differential Diagnoses—Ovid Otto Meyer, Chairman, Department of Medicine, University of Wisconsin, Madison

10:15 *Intermission*

Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

11:00 *Panel Discussion:* EMBOLIC PHENOMENA AND THEIR TREATMENT..General Lecture Hall
Moderator: James S. McCartney, Minneapolis
Thrombophlebitis } —Herman O. McPheeters, Minneapolis
Thrombosis }
Dicumarol and Heparin—Nelson W. Barker, Rochester

P.M. *Afternoon*

12:15 Obstetric Manikin Demonstration.....Admiral Room, Hotel Radisson
(Luncheon Meeting)
Harold L. Gainey, Assistant Professor, Obstetrics and Gynecology, University of Kansas School of Medicine, Kansas City

1:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

2:00 *Panel Discussion:* SURGERY OF INJURIES.....General Lecture Hall
Moderator: Edward T. Evans, Minneapolis
Injuries of the Hand and Forearm—Michael L. Mason, Associate Professor of Surgery, Northwestern University Medical School, Chicago
Bladder Injuries—Baxter A. Smith, Jr., Minneapolis
Abdomino-Thoracic Injuries—Nathan K. Jensen, Minneapolis
Head Injuries—Wallace P. Ritchie, St. Paul
Injuries of the Lower Extremeties—Henry H. Young, Rochester

3:15 *Intermission*

Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

4:00 *Russell D. Carman Memorial Lecture*.....General Lecture Hall
Subject: THE ROLE OF X-RAY PELVIMETRY IN OBSTETRICS—Paul Chesley Hodges, Professor of Radiology, Department of Medicine, University of Chicago
Presentation of Speaker: H. Milton Berg, Bismarck, N. D., President, Minnesota Radiological Society

5:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

5:15 Obstetric Manikin Demonstration.....Lecture Hall, Mezzanine Floor
Harold L. Gainey, Assistant Professor, Obstetrics and Gynecology, University of Kansas School of Medicine, Kansas City

8:00 "A MIDSUMMER DREAM".....Ballroom, Hotel Radisson
(Listed under Section II—Special Session)

Monday, June 7

SECTION II—SPECIAL SESSION

A.M.

9:00 *Orthopedic and Fracture Surgery*.....Lecture Hall, Mezzanine Floor
Chairman: Edward T. Evans, Minneapolis
Subject: SURGERY OF EMERGENCIES
Abdomino-Thoracic Injuries—Lyle J. Hay, Minneapolis, and Nathan K. Jensen, Minneapolis
Head Injuries—Wallace P. Ritchie, St. Paul

10:15 *Intermission*

Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

11:00 *Orthopedic and Fracture Surgery,* (Continued).....Lecture Hall, Mezzanine Floor
Hand and Forearm Injuries—Michael L. Mason, Associate Professor of Surgery, Northwestern University Medical School, Chicago

P.M. *Afternoon*

12:15 Obstetric Manikin Demonstration.....Admiral Room, Hotel Radisson
(Luncheon Meeting)
Harold L. Gainey, Assistant Professor, Obstetrics and Gynecology, University of Kansas School of Medicine, Kansas City

1:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

2:00 American College of Chest Physicians, North Midwest Chapter.....Lecture Hall, Mezzanine Floor
Moderator: J. Arthur Myers, Minneapolis
Dangers of Delay in the Diagnosis of Indeterminate Pulmonary Lesions—C. Allen Good, Rochester
Discussion: E. P. K. Fenger, Oak Terrace, and Thomas Lowry, Minneapolis
Some Experiences with Streptomycin in the Treatment of Tuberculosis in the Veterans Administration—William B. Tucker, Minneapolis
Discussion: Russell Frost, St. Paul, and Karl Pfuetze, Cannon Falls

3:15 *Intermission*

Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

4:00 *American College of Chest Physicians,* (Continued)...Lecture Hall, Mezzanine Floor
Nebulization Therapy for Pulmonary Diseases—Arthur Olsen, Rochester
Discussion: J. Arthur Myers, Minneapolis, and G. A. Hedberg, Nopeming
Diagnosis of Peripheral Lung Tumors Observed in Chest Survey—David Sharp and Robert Nord, Minneapolis
Discussion: William Roemmich, Minneapolis, and Sumner S. Cohen, Oak Terrace

5:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

5:15 Obstetric Manikin Demonstration.....Lecture Hall, Mezzanine Floor
Harold L. Gainey, Kansas City

8:00 "A Midsummer Dream".....Ballroom, Hotel Radisson
For the members of the Minnesota State Medical Association and their wives and all convention visitors . . .

At eight o'clock on the evening of June 7, 1948
The Dayton Company of Minneapolis
will present
"A Midsummer Dream"
featuring fashions for summer, 1948, with a background
of music by Fred Oldre and his orchestra
Dancing from nine to twelve in the Ballroom to the
music of Fred Oldre and his orchestra.

Tuesday, June 8

SECTION I—GENERAL SESSION

A.M.

8:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

9:00 *Clinical-Pathological Conference*.....General Lecture Hall
Subject: Acute Abdominal Pain
Presentation of Cases—Arthur H. Wells, Duluth
Differential Diagnosis—Walter G. Maddock, Northwestern University Medical School, Chicago

10:15 *Intermission*

Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

11:00 *Panel Discussion:* Nutrition in Surgery.....General Lecture Hall
Moderator: Albert M. Snell, Rochester
Parenteral Feeding in Surgery—Walter G. Maddock, Northwestern University Medical School, Chicago
Entoral Feeding—Richard L. Varco, Minneapolis

P.M. *Afternoon*

12:15 Obstetric Manikin Demonstration.....Admiral Room, Hotel Radisson
(Luncheon Meeting)
Earl C. Sage, Professor of Obstetrics and Gynecology, University of Nebraska School of Medicine, Omaha

12:15 Round Table Luncheons.....Hotel Radisson
(Listed under Section II—Special Session)

1:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

2:00 *Panel Discussion:* ANTIBIOTICS ..... General Lecture Hall
Moderator: Wesley W. Spink, Minneapolis
Present Trends in Penicillin Therapy—Samuel H. Boyer, Jr., Duluth
Streptomycin and Newer Antibiotics in Infections Other Than Tuberculosis—Wallace E. Herrell, Rochester
Streptomycin in Tuberculosis—Karl Pfuetze, Cannon Falls
Summary—Wesley W. Spink, Minneapolis

3:15 *Intermission*

Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

4.00 *Pediatrics Lecture:* ST. LOUIS ENCEPHALITIS ..... General Lecture Hall
Russell J. Blattner, Professor of Pediatrics, Baylor University College of Medicine, Houston, Texas
Presentation of Speaker: Irvine McQuarrie, Minneapolis, representing the Northwestern Pediatrics Society

5:00 Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

5:15 Obstetric Manikin Demonstration ..... Lecture Hall, Mezzanine Floor
Earl C. Sage, Professor of Obstetrics and Gynecology, University of Nebraska School of Medicine, Omaha

5:00 SOCIAL HOUR PRECEDING THE BANQUET
Five to Six-Thirty o'clock in the
Italian Room, Hotel Radisson

Mr. George Ulmer, President, Physicians and Hospitals Supply Company and the Ulmer Pharmacal Company of Minneapolis. EVERYBODY is invited to attend.

7:00 *Annual Banquet* ..... Ballroom, Hotel Radisson
(Listed under Section II, Special Session)

Tuesday, June 8

SECTION II—SPECIAL SESSION

A.M.

9:00 *Symposium on Research Problems* ..... Lecture Hall, Mezzanine Floor
Chairman: James T. Priestley, Rochester
Treatment of Leukemia with Urethane—Howard Horns, Minneapolis
The Extraction of Secretion from the Intestine of Man—A. H. Baggenstoss, Rochester
Fundamental and Clinical Aspects of Pulmonary Hypertension—Craig Borden, Minneapolis
Measurement of Portal Vein Pressure in the Intact Animal—F. W. Hoffbauer, Minneapolis, and J. L. Bollman and John Grindlay, Rochester
Experiences with Screening Tests in the Detection of Cancer—David State, Minneapolis

10:15 *Intermission*

Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

11:00 *Symposium on Research Problems* (Continued) ..... Lecture Hall, Mezzanine Floor
Extrarenal or Prerenal Azotemia—John La Bree, Minneapolis
Clinical Measurement of the Viscosity of the Plasma—Frank D. Mann, Rochester
Effect of Vagotomy on Intestinal Motility—S. Faik, Rochester
Fluorescein in the Diagnosis of Brain Tumors—George Moore, Minneapolis

P.M. *Afternoon*

12:15 Obstetric Manikin Demonstration ..... Admiral Room, Hotel Radisson
(Luncheon Meeting)
Earl C. Sage, Professor of Obstetrics and Gynecology, University of Nebraska School of Medicine, Omaha

12:15 Round Table Luncheons ..... Hotel Radisson
Common Skin Diseases—Merriam G. Fredricks, Duluth
Hypertrophies in Children—Paul F. Dwan, Minneapolis
The Nervous Patient—Francis J. Braceland, Rochester
Radioactive Iodine in the Treatment of Thyroid Disease—Charles E. Rea, St. Paul
Antihistamine Drugs—Bayard T. Horton, Rochester
Management of Hand Infections—Michael L. Mason, Chicago
Ménière's Disease and Vertigo—Lawrence R. Boies, Minneapolis
Insulin Mixtures—John R. Meade, St. Paul
Urethane, Nitrogen Mustard—Edmund B. Flink, Minneapolis

2:00 *Minnesota Academy of Ophthalmology and Otolaryngology* ..... Lecture Hall, Mezzanine Floor
Plastic Submucous Resection Otoplasy—Dean McAllister Lierle, Professor of Otolaryngology, State University of Iowa, College of Medicine, Iowa City

3:15 *Intermission*

Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

4:00 *Minnesota Academy of Ophthalmology and Otolaryngology* (Continued) ..... Lecture Hall, Mezzanine Floor
Histamine in Ophthalmology and Otolaryngology—Bayard T. Horton, Rochester

5:00 Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

5:15 Obstetric Manikin Demonstration ..... Lecture Hall, Mezzanine Floor
Earl C. Sage, Professor of Obstetrics and Gynecology, University of Nebraska School of Medicine, Omaha

5:00 Social Hour Preceding Banquet ..... Italian Room, Hotel Radisson
Through the courtesy of Mr. George Ulmer, President, Physicians and Hospitals Supply Company and the Ulmer Pharmacal Company of Minneapolis

7:00 Annual Banquet ..... Ballroom, Hotel Radisson
Presiding: Ralph H. Creighton, Minneapolis, President, Hennepin County Medical Society
Presentation of guests
Introduction of Mrs. Harold F. Wahlquist, Minneapolis, President, Woman's Auxiliary
Presentation of Southern Minnesota Medical Association Medal
Presentation of Distinguished Service Medal
Presidential Address: "The New Look in Medicine," A. E. Cardle, Minneapolis, President, Minnesota State Medical Association
"Medicine—A Force for Peace"—Nicholas Amtoroff, R.S.B.T., New York

Wednesday, June 9

Section I—General Session

A.M.

8:00 Scientific Cinema ..... West Corridor.
Visit Scientific and Technical Exhibits

9:00 *Clinical-Pathological Conference* ..... General Lecture Hall
Subject: Uterine Bleeding
Presentation of Cases—John L. McKelvey, Minneapolis
Differential Diagnoses—Erle Henriksen, Associate Professor of Gynecology and Consulting Pathologist, University of Southern California, Los Angeles

10:15 *Intermission*

Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

11:00 *Arthur H. Sanford Lecture in Pathology* ..... General Lecture Hall
Subject: Rheumatic and Bacterial Endocarditis—Benjamin J. Clawson, Minneapolis
Presentation of Speaker: A. H. Baggenstoss, Rochester, President, Minnesota Society of Clinical Pathologists

P.M. *Afternoon*

12:15 Obstetric Manikin Demonstration ..... Spanish Room, Hotel Radisson
(Luncheon Meeting)
John E. Faber, Rochester

12:15 Round Table Luncheons ..... Hotel Radisson
(Listed under Section II, Special Session)

1:00 Scientific Cinema ..... West Corridor
Visit Scientific and Technical Exhibits

2:00 *Public Health Meeting:* An Unfinished Job ..... General Lecture Hall
Chairman: A. E. Cardle, Minneapolis, President, Minnesota State Medical Association
Our Part in These Times—John O. Christianson, D.Sc., Superintendent, University of Minnesota School of Agriculture, St. Paul
The First Line of Defense—Lloyd E. Harris, Rochester
National Health Legislation—Senator Joseph H. Ball, Washington, D. C.
Budgeting for Health Care—Robert L. Novy, President, Michigan Medical Service, Inc., Detroit
Teamwork in the Conservation of Human Resources—Morris Fishbein, Editor, *Journal of the American Medical Association,* Chicago

Wednesday, June 9

Section II—Special Session

A.M.

11:00 *Minnesota Heart Association* ..... Lecture Hall, Mezzanine Floor
Chairman: Paul F. Dwan, Minneapolis, President, Minnesota Heart Association

P.M. *Afternoon*

12:15 Obstetric Manikin Demonstration.....Spanish Room, Hotel Radisson
(Luncheon Meeting)
John E. Faber, Rochester

12:15 Round Table Luncheons.....Hotel Radisson
Lobotomy—Wallace P. Ritchie, St. Paul
Liver Function Tests—Herman J. Wolff, St. Paul
Pelvic Pain—Erle Henriksen, Los Angeles
Office Procedures in Rectal Diseases—Walter A. Fansler, Minneapolis
Newer Drugs—Raymond N. Bieter, Minneapolis
Common Urinary Problems—John L. Emmett, Rochester
Eye Ground Findings in Everyday Practice—Virgil J. Schwartz, Minneapolis
Facts and Fallacies Concerning the Thymus Gland—George B. Logan, Rochester
Treatment of Heart Disease—Paul G. Boman, Duluth

1:00 Scientific Cinema.....West Corridor
Visit Scientific and Technical Exhibits

2:00 Public Health Meeting: An Unfinished Job.....General Lecture Hall
(Listed under Section I—General Session)
A special health conference entitled "An Unfinished Job" will conclude the convention program. Invited to hear distinguished guest speakers discuss health problems, showing medicine's responsibility and the interplay of other factors influencing health and welfare, will be members of allied health organizations, social welfare workers, school and government authorities and representatives from the co-operative, farm, labor, professional and civic groups.

Meeting of January 8, 1948

Dr. L. Haynes Fowler, Presiding

CARCINOMA OF THE GALL BLADDER

An Analysis of 70 Cases

EDWIN G. BENJAMIN, M.D.
Minneapolis, Minnesota

This study was made by checking records in four institutions: thirty cases from the University of Minnesota Hospitals, twenty from the Minneapolis General Hospital, twelve from Northwestern Hospital, and eight from St. Barnabas Hospital, all of Minneapolis. All of the cases included in this study were proven by operation or autopsy. No case was included where the information was inadequate or the diagnosis questionable. Only cases from the past decade, from 1937, were included in this study.

Incidence

The exact incidence of carcinoma of the gall bladder is somewhat difficult to determine. Some authors have given it fifth place in frequency of cancer among the organs of digestion. The order is as follows: (1) stomach, (2) colon and cecum, (3) rectum, (4) esophagus, (5) gall bladder and ducts.[11] Carcinoma of the gall bladder has a tendency to occur more frequently in women than in men. It has been estimated to account for between 8 and 10 per cent of all cancer in women. A study of autopsy records at the department of pathology at the University of Minnesota, for the period 1937 through 1946, shows that out of 25,283 consecutive autopsies, carcinoma of the gall bladder was listed as the cause of death eighty-four times, an incidence of 0.33 per cent. This figure corresponds with other reports in the literature.

Age and Sex

The incidence of carcinoma of the gall bladder is considerably higher in women than in men. The greater incidence in women is thought by many to result from the greater preponderance of gallstones in females. In this series, the disease was found in forty-seven females and twenty-three males—the ratio being a little more than two to one. The usual ratio is given as three women to one man.

Carcinoma of the gall bladder is definitely a disease of the so-called "cancer age." It almost always occurs in a patient over forty years of age. The average age in various reported series ranges from fifty-seven to sixty-five. The youngest patient reported was a man twenty-two years of age, while the oldest was a woman of ninety-three. All patients in this series were over forty. The youngest was forty-three and the oldest eighty-three. The average age for this series is sixty-two years.

TABLE I. AGE AND SEX

Age	Male	Per cent	Female	Per cent	Total	Per cent
41-50	4	5.7	3	4.2	7	10
51-60	6	8.5	14	20.0	20	28.5
61-70	8	11.4	17	24.2	25	35.7
71-80	4	5.7	12	17.1	16	22.8
81	1	1.4	1	1.4	2	2.8
Total	23	32.8	47	67.2	70	100.0

Symptomatology

The symptoms associated with carcinoma of the gall bladder are variable, depending on the location and extent of spread of the lesion. The most common symptoms in the order named are: pain, weight loss, weakness, anorexia, nausea, vomiting, jaundice, and the presence of a mass. Other symptoms seen less frequently are diarrhea, constipation, bloating or belching, chills and fever, and tarry stools.

The duration of the symptoms varies greatly. Most of the patients in this series had complaints of more than one month duration, but less than six months. A number of patients seemed to be acutely ill at the onset, their symptoms being present only for a few days or weeks. Several patients never had any acute symptoms whatever, but complained of vague abdominal distress for several years. Many had a history of acute biliary colic many years previously, with or without jaundice, which cleared up spontaneously and never reoccurred. Three of the patients in this series had previous gall-bladder operations; two had their gall bladders removed, and one had a drainage with removal of stones. One patient had an incision of a subdiaphragmatic abscess, which subsequently developed a biliary fistula.

TABLE II. DURATION OF SYMPTOMS

Under 1 month	14
1-6 months	34
6 months to 1 year	12
To 5 years	10

Where a careful history had been taken, some interesting facts were elicited. Very often, where the acute symptoms had been present for a relatively short time, it was revealed, on close questioning, that the patient had had digestive disturbances over a period of many years. Food intolerances were noted in many instances.

Inaugural thesis.

Constipation with the use of cathartics was common. A number of patients had sought medical advice for their discomfort. Some had been given medications without adequate examination to determine the cause of their trouble. Others had had extensive studies, including laboratory and x-ray. Of these, several had had definite diagnoses made of gall-bladder disease, including the presence of gallstones. Some had been advised to have an operation performed, but had refused. In such cases it is interesting to speculate whether or not such an unfortunate development as carcinoma of the gall bladder would have occurred if the patients had heeded the advice given them.

Pain was the most frequent complaint. It was present in 85 per cent of the cases in this series. It is located in the right upper quadrant and the epigastrium. Once the pain has become noticeable, it is usually constant, dull, and persistent. It is often described as a burning sensation, fairly definitely localized and usually not radiating. It is quite distinct from the pain of biliary colic, although colic was present in some of these patients.

Jaundice was seen in thirty-four of the patients in this series, an incidence of forty-eight per cent. Once jaundice has developed, it is usually continuous. Clay-colored stools and dark urine have usually been noted by the patient even before the jaundice has become pronounced. Pruritus was a common accompaniment, and was very distressing in several of the cases. The icteric index rises rapidly, very commonly over 100 and much higher in some instances.

Weight loss was a common complaint. It was present in 64 per cent of the cases in this study. Weight loss, weakness and anorexia are present in nearly all cases of cancer. In this series, weight loss was a prominent feature and was the first symptom in some instances. The weight loss was more profound where the gastrointestinal disturbance was severe. The average weight loss where this symptom was mentioned was 26.3 pounds. One man, who had a large mass present, lost 60 pounds in a period of four months.

A palpable *mass* was found to be present in thirty-four cases (48 per cent). It was usually firm and tender and sometimes attained considerable size. The liver edge could be palpated in nearly half of the cases. It was felt in all those with jaundice, and in some cases definite nodules could be palpated. The nodules were present in the advanced cases and probably represented metastases.

Anemia was not a prominent finding in this series. The average hemoglobin was 76 per cent. One hemoglobin was reported as 36 per cent—this in a patient who had bleeding into the bowel, as evidenced by tarry stools. The autopsy showed the carcinoma had perforated the duodenum. One patient had a hemoglobin of 107 per cent. This was probably due to dehydration from vomiting.

Causative Role of Gallstones

As with carcinoma elsewhere, the specific etiological factors in carcinoma of the gall bladder are not known. The relationship between carcinoma of the gall bladder and gallstones must be considered to be very important. In various reported series, the majority of cases show that stones have antedated the development of the malignancy. There is, in all probability, an irritation produced by the calculi which influences the production of the neoplasm.[9] It is obvious that cholelithiasis is not the only and direct cause of the carcinoma, for we see many patients with gallstones and inflammation of the gall bladder of many years' standing who do not develop malignancy. The role of stones as an exciting factor seems definite. The incidence of cases of cholelithiasis in which carcinoma finally developed has been estimated variously from 1.14 to 15 per cent.[11]

TABLE III. INCIDENCE OF GALLSTONES IN 70 CASES OF CACRINOMA OF THE GALL BLADDER

	Stones Present			*Stones Absent*		
	Number	Per cent	Average Age	Number	Per cent	Average Age
Males	8	12	64	15	21.5	59
Females	32	45	65	15	21.5	61
Total	40	57	64.5	30	43	60

In this group of cases, stones were definitely demonstrated in only 57 per cent of the cases. However, it should be remembered that many of these patients had the diagnosis made at operation where an extensive exploration was not done. It is the belief of this writer that this figure would be much higher if all of the cases reported were the result of autopsy findings. Where inoperable carcinoma was found, the incision was closed in many instances with no attempt being made to determine the presence or absence of stones.

If we consider only the autopsy reports, our figures are much different. It is admitted that surgical statistics are misleading, for, as stated, inoperable malignancies cannot be satisfactorily explored. In this series thirty-eight patients came to autopsy. Cholelithiasis was reported in thirty-one of the thirty-eight. Thus, stones were present in 81.3 per cent of the autopsied cases. This figure corresponds to those reported in the literature.[11]

Experimental studies on gall bladders of laboratory animals, in an attempt to produce carcinoma by the introduction of foreign bodies, have been undertaken by several authors. The results have, in the main, been inconclusive. Petrov and Krotkina were able to demonstrate carcinoma in five out of 100 guinea pigs after the introduction of sterile, hard, foreign bodies (which act like gallstones in the human).[12] This would lead us to agree with Graham, who advocates prophylactic removal of gall bladders for gallstones, even though they be of the so-called "silent" variety.[7]

Pathology

In most of the patients operated on, the presence of malignancy was determined readily by gross examination. In only two cases was a gall bladder removed for chronic cholecystitis and cholelithiasis, to have the diagnosis of carcinoma made by microscopic examination. It is a tribute to the diagnostic ability of the clinicians that

the true condition was suspected in all of the remaining cases.

In most instances the gall bladder was found to be enlarged, thick-walled, shaggy, and to contain thick bile. In several there was direct extention to the liver bed. In two cases, there were biliary fistulas. One patient had a perforation into the duodenum. Four had obstruction of the duodenum. Forty-two had metastases to the liver and/or nodes. The majority of the cancers were of the adenocarcinoma type, where the type was stated. Three scirrhous and two squamous cell carcinomas were reported.

No attempt was made to classify the type of carcinoma according to Broder's method. This might have been useful, as some surgeons are able to estimate the probability of metastases and the relative length of life of the patient following surgery. In some instances it may have been of value in determining the type of operation to be performed.

Diagnosis

The difficulty of establishing a diagnosis of carcinoma of the gall bladder preoperatively is readily apparent. Except when advanced, the clinical picture is one of benign biliary disease. A typical instance could be summarized as follows:

A woman, aged 60, with a past history of epigastric distress, begins to notice continuous pain in the right upper quadrant. There is belching, regurgitation, fullness associated with anorexia, and weakness. There may have been a few attacks of biliary colic, and there may be weight loss, nausea, vomiting, and possibly jaundice. The onset is indefinite and insidious. The fact that the jaundice is associated with pain does not rule out malignancy. The jaundice in malignancy does not usually come on suddenly, as is true with that seen where there is blockage from a stone. The presence of a mass must be regarded as a late sign.

Laboratory work and x-rays are of little help in establishing a diagnosis. Many of the cases in this series had very extensive laboratory studies. Also they had the benefit of competent medical consultations. It is fair to state that in no case was an early diagnosis made which could have led to an earlier operation, thus making it possible to eliminate the cancer before an extensive spread had taken place. It is an accident when a carcinomatous gall bladder is removed prior to its involving the liver or ducts.

The icteric index or serum bilirubin determinations were made in practically all patients in this series who had jaundice. They were, of course, found to be elevated, but the results give no information as to the presence of carcinoma. Many patients had extensive liver function tests, but here again the findings gave only a clue as to the presence of liver damage and no specific information of the cause of the trouble could be obtained. Practically all other laboratory tests gave similar lack of helpful evidence. The majority of patients had preoperative x-ray studies—some very extensive. Here, again, the results were disappointing and the findings were of little aid. Several patients had gall-bladder studies reported as entirely normal. Several patients had nonfunctioning gall bladders, and stones were demonstrated in a few. In no case, however, was the roentgenogram an aid in determining the nature of the disease. Gastrointestinal x-rays were made in many cases, and were not of any particular help.

Surgery

The type of operation selected in cases where a carcinomatous process involves the gall bladder depends on the individual case. As has been stated, most of the cases in this series were inoperable and only exploration and biopsy were carried out. The operation may be palliative, or, if the condition permits, a radical attempt may be made to extirpate the neoplasm. The palliative procedure may concern itself with an attempt to reestablish the normal flow of bile where an obstruction exists. This, at best, is only a temporary expedient, but it will serve to clear up jaundice and relieve the patient of troublesome pruritus. If the normal flow of bile cannot be restored, then a cholecystostomy may be done. Various types of anastomoses have been attempted where the common duct was involved. These include cholecystogastrostomy, cholecystoduodenostomy, and cholecystojejunostomy. If the situation lends itself to reconstruction of the bile ducts, some such method as that advocated by Cole,[3] with the use of vitallium tubes, or the method devised by Allen, with anastomosis of the proximal duct to the jejunum,[2] may be used.

No radical procedures were performed on the patients operated on in this series. Different types of operations have been described, and might be useful in selected cases. These operations appear to be most formidable. In most cases it would involve the resection of a portion of the liver, as the carcinoma usually invades the liver early in the disease, spreading by direct extension. It must be admitted that extensive involvement of the liver and bile passages with carcinoma is one of the most hopeless situations confronting a surgeon. Brunschwig and Bigelow have advocated excision of the gall bladder and ducts.[1] Payne has reported cases where a portion of the liver has been resected. Some modification of a Whipple operation has been attempted. At the present writing, these procedures have not given any great hope. It is really questionable whether the average length of survival of the patients subjected to these operations is any better than those who have received nonoperative treatment only.

Summary

Seventy cases of carcinoma of the gall bladder are presented. Twenty-three were in men and forty-seven were in women. The average age was sixty-two years.

The clinical picture was not well defined but resembled that of benign biliary disease in the early stages.

Of the seventy patients there were forty-five who had operations performed and thirty-eight came to autopsy. The incidence of calculi in the entire group was 57 per cent while the percentage was 81.3 in the autopsy group.

Operative procedures may be palliative or radical. It is doubtful whether the radical procedures are justified except in highly selected early cases. In view of the difficulty of diagnosis good results can rarely be expected.

The prognosis of carcinoma of the gall bladder is poor. Inasmuch as the incidence of malignancy is between 4

and 5 per cent of calculous gall bladders, the only hope for reduction of the general incidence lies in early removal of calculous gall bladders. This procedure is justified because modern surgical methods have reduced the operative mortality for cholecystectomy to less than 1 per cent.

Discussion

Dr. Hamlin Mattson: Dr. Benjamin should be commended for this study of carcinoma of the gall bladder in this area for a ten-year period. A few years ago I made a similar study and know the amount of work which is involved. Mine was largely necropsy data. The earlier surgeons found carcinoma of the gall bladder more than we do. The literature is replete with pathologic and necropsy studies but contains little on early diagnosis and surgical treatment. Perhaps the best surgical treatment is indicated by the fact that in the earlier years when the gallstones were permitted to battle it out with the body, there was a greater instance of carcinoma. Therefore the best treatment is removal of the calculous gall bladder whenever possible. The person who has a cholecystectomy because of stones and in whom an early cancer of the gall bladder is found is fortunate indeed.

When carcinoma is confined to the gall bladder itself, cholecystectomy and removal of adjacent liver tissue is advisable. In advanced cases, peritoneoscopy rather than laparotomy seems indicated.

A study of this type is beneficial, in that it reminds us that there is no such thing as an innocent gallstone.

Dr. A. A. Zierold: My experience with carcinoma of the gall bladder has been a small one. Within the past ten years the incidence of carcinoma of the gall bladder was no more than a fraction of 1 per cent in the cases of gall-bladder disease in which I have operated. I don't believe that the average individual sees a sufficient number of such cases to give him a background for very extensive comment. Such collections as these, and as Doctor Mattson related, will indicate some trends. I believe that we can say that it is probable that the presence of stone in the gall bladder does have something to do with the incidence of carcinoma, but I believe that the incidence is so low that the evidence merely indicates a trend.

I believe there is one thing that has not been emphasized in the series of Doctor Benjamin, and that is—early and late the picture of carcinoma involving the biliary tract is the picture of carcinoma elsewhere. Anorexia and weight loss are outstanding and without apparent cause. Remedial surgery appears to be beyond us at this particular time. Palliative surgery, except in a few cases, also is a thankless undertaking. In the individual who is so far advanced in his disease as to make survival questionable, little or no damage may be done by exploratory examination, but some damage may be done by peritoneoscopy. In my hands, this procedure is of limited diagnostic value.

I think Doctor Benjamin should be congratulated on this paper. It represents a great deal of work, unavoidable drudgery, and considerable interest to carry it through as completely and logically as he has done.

THE ROLE OF NARCOTICS (MORPHINE) IN POSTOPERATIVE MORBIDITY

J. H. STRICKLER, M.D., and CARL O. RICE, M.D., Ph.D.
Minneapolis, Minnesota

In addition to analgesia, narcotics have many other physiologic effects which have, individually, been the subject of numerous laboratory and clinical investigations. Knowledge of their total influence on postoperative morbidity has been mainly speculative. The relief of pain is essential, yet other concomitant physiologic actions of narcotics, such as depression of cough, smooth muscle spasm, et cetera, may initiate a chain of events cumulating in a detrimental result. It is the purpose of this study to evaluate the benefits and the disadvantages of the postoperative use of narcotics by an analysis of postoperative morbidity. Morphine and codeine were used almost exclusively. In occasional instances where other analgesics were used they were given a proportionate value and added to morphine in computing total dose.

Method of Investigation

Three hundred and sixty-eight cases of uncomplicated intra-abdominal operations were selected, first by running a series with morphine, then one without. In four instances, cases begun in the no-morphine series did receive morphine in their postoperative course to relieve pain. These cases were left in the no-morphine group to avoid transferring their complications, possibly associated with pain, into the narcotic group. Those cases receiving no narcotics were given a barbiturate and atropine as preoperative medication and intravenous alcohol, 6 per cent, for postoperative analgesia. In occasional instances 1.0 gm. of sodium salicylate was given intravenously as a supplement to the alcohol, based on the evidence of synergism of the two drugs as noted by Wolff and Hardy.[22]

In order to obtain uniformity as to type of cases and thereby avoid the pitfalls of too many variables, and still not extend the study over too long a time, it was decided to make observations on intra-abdominal surgical cases. This series was further simplified by the exclusion of pediatric patients, patients with suppuration noted preoperatively or at operation, and cases involving bowel resection. When nasal suction or an inlying urinary catheter was used prophylactically, the case was not included, since certain complications thereby would have been averted. Antibiotics were used only for treatment of complications. All patients received inhalation anesthesia.

Table I lists the distribution of cases as to type of surgical procedure. A separate listing was kept of all

This study was conducted at the St. Barnabas Hospital as part of the training program for surgical residents.

the patients operated upon by one surgeon (Dr. X) so that variation of technique and postoperative management might be ruled out in a comparison of his group to the total series. These graphic comparisons (Figs. 5, 7, 9 and 11) in the series of Dr. X indicate a similar trend with the over-all series, with differences persisting from day to day, which in itself bears considerable significance. Had there been a larger series of cases, the significant difference probably would have been more evident.

For further analysis of the data, an arbitrary line was established to obtain comparison between high and low doses of morphine as well as none and any. One-half grain of morphine or a comparable dose of codeine, et cetera, was selected as the division, above which the dose was considered high.

Since actual diagnosis of complicating disease, such as atelectasis, pneumonia, pulmonary infarct, phlebothrombosis, et cetera, often is equivocal, and the incidence of the occurrence of a full-blown case is so infrequent, it was decided to pay more attention to the more frequenttly occurring and more easily observed signs and symptoms. Fever, cough, gas pains, vomiting, urinary retention, diarrhea, and chest pain all indicate bodily disorder and are either the signs of, or the precursors to, the more serious postoperative complications.

Of the 368 cases, 277 were given morphine as required for relief of pain as preoperative medication, or as a routine medication every four hours after operation. Ninety-one patients received no morphine at all. In the series of 141 cases of Dr. X, ninety received morphine and fifty-one got none. To evaluate the differences between these groups and to place proper weight or balance with groups of different sizes, statistical methods were employed. For assay of the percentile observations, the Edgerton-Patterson frequency distribution chart was used, and a difference of 2.5 standard deviations, i.e., critical ratio, was considered significant. In evaluating the differences of mean daily temperatures (Figs. 7 and 8), the formlas

$$K = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{Sx^2}{Nx} + \frac{Sy^2}{Ny}}} \qquad \text{and} \qquad Sx^2 = \frac{\Sigma x^2}{N} - \bar{x}^2$$

were used. K of greater than 1.96 was taken to be significant.

Graphs of the mean percentage incidence of cough, gas pains, catheterization for urinary retention, and emesis were plotted for the day of surgery and the following ten postoperative days. The statistical significance of the differences on each day was computed. The graphs are self-explanatory, but attention should be called to the days on which a significant difference occurred between the morphine and no-morphine curves.

TABLE I. COMPOSITE PICTURE OF 368 CASES

Divided into three series—all cases, those receiving narcotics (high-low dose) and those of Dr. X. The comparative incidence of complications can be noted.

	All Cases—368						
	Inactive Appendix	Acute Appendix	Gynecology Cases	Chole-cystectomy	Hernior-rhaphy	Miscel-laneous	Totals
None	13	22	23	10	19	4	91
Low	20	25	30	11	21	4	111
High	24	26	55	29	21	11	166
Total	57	73	108	50	61	19	368
	Cases of Dr. X—141						
None	13	21	23	10	19	4	90
Any	6	12	12	11	8	2	51
Total	19	33	35	21	27	6	141

Since an elevated temperature is indicative of bodily disorder of many possible sources, a difference in this sign should be important. Differences in mean peak daily temperatures are represented graphically in Figures 1 and 2, Figure 1 being the difference between none and any morphine and Figure 2 between high, low, and no doses. Statistical evaluation of differences on each individual day failed to exceed the critical ratio, but the persistence of even small differences, when repeated consecutively, gains considerable significance. A definite difference persists between the first and sixth postoperative days.

A scatter graph (Fig. 3) was compiled to demonstrate possible relationship of total dose of narcotic to days of fever, i.e., postoperative days until temperature remained at 99° or less. It is noted that there is roughly a distribution upward and to the right, indicating some correlation between higher total dosage and days of fever. It is possible, however, that an unsound conclusion might be drawn from this, since patients with complications probably required more prolonged analgesia. It is presented only as another view of the data for whatever it may be worth.

Results of the Study

Table II represents a listing of complicating symptoms, signs and diseases as a composite picture of the entire hospital course. The morphine group had 1.7 days more of fever, 0.51° higher than mean peak temperatures, et cetera. The line indicating average number of times or days of catheterization, cough, et cetera, takes into account the severity and duration of the complication, whereas percentage incidence accounts only for the number or percentage of patients exhibiting the symptom. The complicating diseases listed, such as pulmon-

ary embolism, atelectasis, et cetera, did not occur frequently enough in either group to be of true statistical significance. However, the difference in percentage of occurrence of sharp chest pain, 11.8 per cent to 5.7 per cent, and of diarrhea, 7.2 per cent to 1.1 per cent, is significant. A comparison of the column of cases of Dr. X to that of the total group is again quite parallel.

TABLE II. DISTRIBUTION OF ALL CASES AS TO TYPE OF SURGICAL PROCEDURE

		All Cases—368		Any Narcotics—277		Dr. X—141	
		No Narcotics 91	Any Narcotics 277	High Dose 166	Low Dose 111	No Narcotics 90	Any Narcotics 51
Days of Fever (Till Temp. 99° or Less)		3.29	4.99	5.54	4.16	3.28	5.00
Peak Temp. (Avg.)		100.08	100.59	100.66	100.48	100.07	100.77
Catheterization	Avg. No. Times	.59	.94	1.08	.73	.59	.98
	% Incidence	21.6	36.4	38.3	33.7	21.6	40.7
Gas Pains	Avg. No. Days	.65	1.36	1.66	.90	.65	1.26
	% Incidence	36.4	60.7	68.9	48.7	36.4	57.5
Cough	Avg. No. Days	.35	1.27	1.46	1.0	.35	1.04
	% Incidence	13.6	21.4	20.4	23.0	13.6	27.8
Emesis	Avg. No. Times	.86	1.01	1.14	.82	.86	.87
	% Incidence	37.5	45.3	49.7	38.9	37.5	37.0
Sharp Chest Pain—%		5.7	11.8			5.7	7.4
Pulmonary Emboli—% (Proved)		0	.4			0	0
Atelectasis or Pneumonia—%		0	4.3			0	3.7
Thrombophlebitis or Phlebothrombosis—%		0	1.1			0	0
Wound Infection—%		0	3.9			0	5.1
Wound Disruption without Infection—%		1.1	4.6			1.1	1.8
Evisceration—%		0	0.4			0	0
Ileus Requiring Suction—%		0	2.8			0	1.8
Diarrhea—%		1.1	7.2			1.1	11.1

None signifies that no narcotic was used. *Low* indicates that a total of ½ grain of morphine, or less, was given throughout the period ofobservation. *High* indicates that more than ½ grain of morphine or comparable dose of codeine was used.

As initially stated, it is not the purpose of this study to determine the causes of the differences observed, but some speculations may be in order based on our knowledge of the pharmacological action of morphine and its derivatives. A review of the literature regarding the observations of other investigators also serves as a basis for such speculations.

Incidence of Cough

The symptom cough attracts particular notice since it exhibits the greatest significant difference between the two groups. There is a greater than 2.5 standard deviation difference from the second through the tenth postoperative day (Fig. 4). Figure 5 illustrates essentially the same findings in the cases of Dr. X. The fact that the statistical significance begins on the second postoperative day must be accounted for.

A possible explanation for this difference in the narcotic and no-narcotic groups may be that morphine suppresses the cough reflex, tends to bronchial muscle constriction,[2,12] diminishes respiratory minute volume, rate and tidal exchange,[9] reduces vital capacity,[8] and decreases the percentage of oxygen saturation of arterial blood.[6] Coughing directly postoperatively is of great value to rid the bronchi of secretions accumulated during anesthesia. The morphine group received the drug, on the average, for two and a half days, and cough did not appear as a significant feature until the second postoperative day. This could be interpreted as narcotic suppression of cough for the first few days, followed by coughing due to, by then, established pulmonary disease resulting from accumulated secretions held within the lungs for too long a time. This situation alone could account for the greater elevation of temperature in the narcotic group.

Incidence of Gas Pains

Gas pains were significantly different in the two series of cases on the first, second and third days (Fig. 6). Figure 7 illustrates essentially the same findings in the cases of Dr. X.

The difference in gas pains is probably related to the spastic influence of morphine on nearly all smooth muscle. Any conclusions regarding intestinal activity may be speculative, because experimental and clinical observations have been made in abnormal situations. Exteriorization of bowel segments, intubation and balloon studies and roentgenography have some unnatural sequalae. A balloon and tube is a foreign body and records only reaction in a particular location. Barium is, likewise, foreign to the bowel and has certain characteristics to which the bowel is not normally accustomed.[1]

Constipation is a well-known effect of morphine compounds. This is due, in part, to slow gastric emptying, pyloric and anal sphincter spasm[12,16] and in part also to dis-co-ordination of the peristaltic and mixing waves of the intestine as a whole.[11] Its effect might be comparable to a spastic constipation.

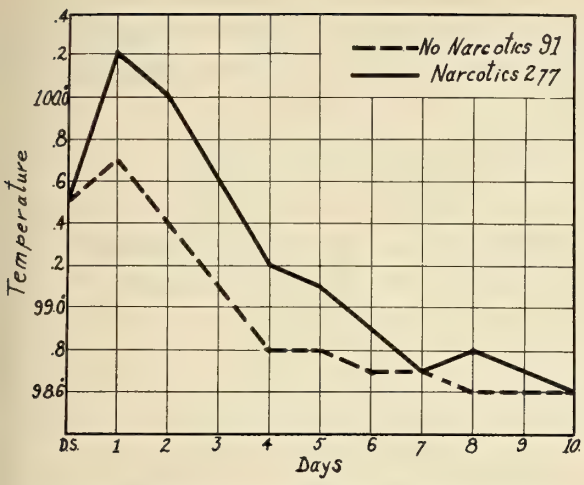

Fig. 1. There was no statistical significant difference in the temperature elevation in the two groups of cases, but the fact that the temperatures were slightly different from day to day lends significance in itself.

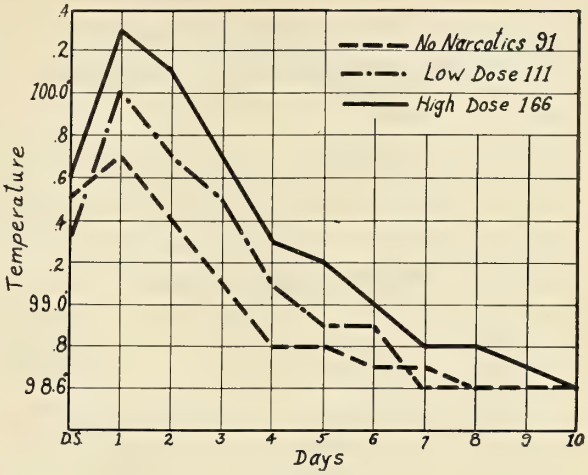

Fig. 2. Temperature difference in high, low and no narcotic series.

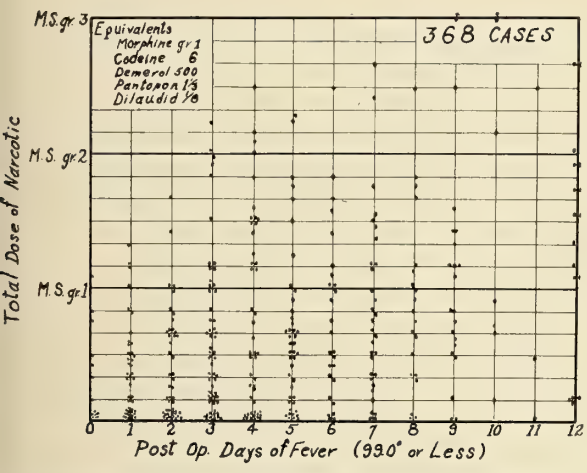

Fig. 3. The scatter graph illustrates a tendency to distribution upward and to the right, suggesting some correlation between a high dose of narcotics and the prolongation of fever.

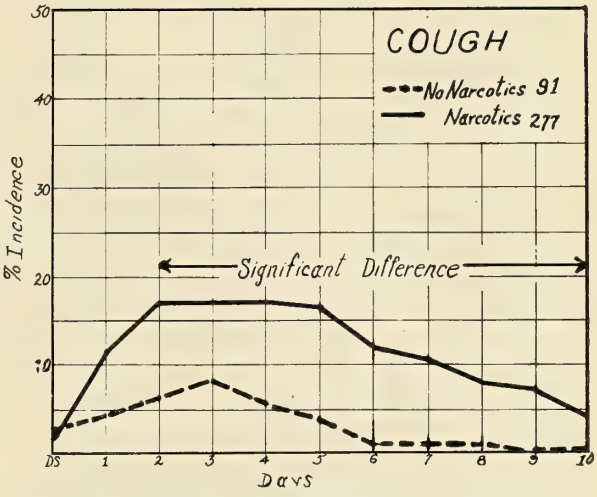

Fig. 4. A statistically significant difference in the incidence of cough with and without the use of morphine is observed from the second to the tenth postoperative day.

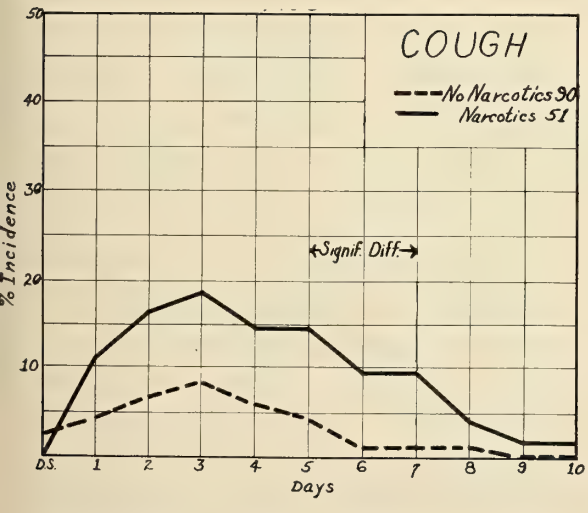

Fig. 5. Cases of Dr. X showing a similar curve to that observed in Figure 4.

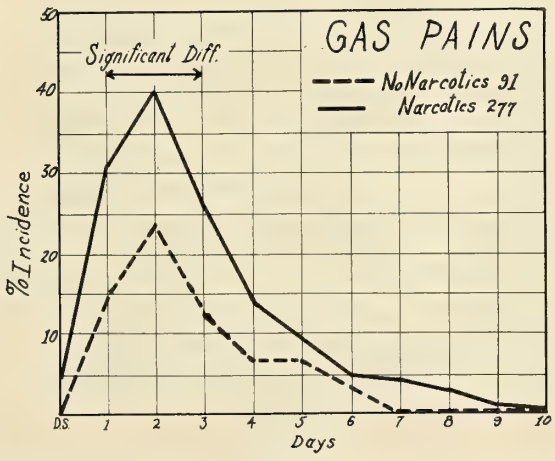

Fig. 6. A statistically significant difference in the incidence of gas pain colic was evident from the first to the third postoperative day.

Most investigators are in agreement that with the use of morphine there is an increased muscular tone in at least one or another of the phases of intestinal muscular activity.[1,2,10,11,12,13,15,18,21,24] Some authors believe that there may be enough spasmogenic effect of morphine on the intestine, at sites other than its sphincters, to produce areas of spasm.[13,18,24]

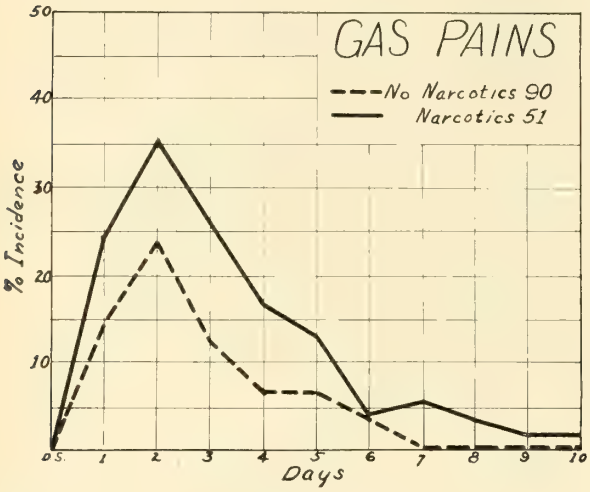

Fig. 7. Cases of Dr. X showing a similar curve to that in Figure 6.

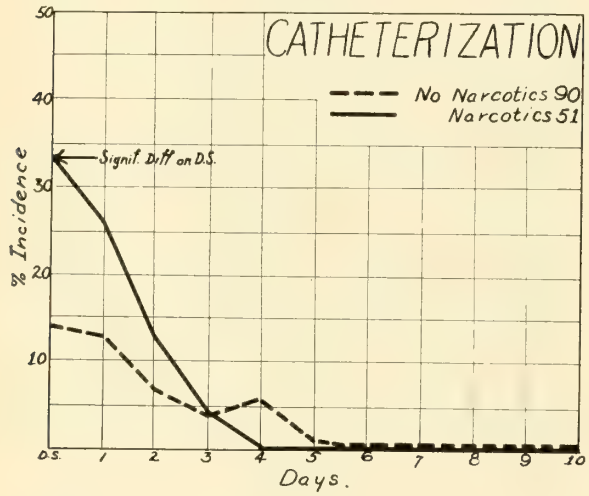

Fig. 9. Cases of Dr. X showing a similar curve to that in Figure 8.

If one carefully differentiates gas pain colic from paralytic ileus, or intestinal obstruction, some confusion is eliminated. In paralytic ileus there is distention without crampy pains, whereas gas pains distention presents an entirely different picture. There are numerous references in the literature which fail to define carefully such terms.[5] Gas pains resemble obstructive colic. In another study we have found x-ray evidence of distention proximal to an area of segmental spasm. We found such areas to be most commonly located at trigger zones in the colon, the hepatic and splenic flexures.

All the abnormal influences of morphine on the intestinal musculature may explain the difference in percentage incidence of gas pains between the two groups involved in this study. Other explanations may be equally or more reasonable. Finally, attention should be called to the fact that some observers believe that there

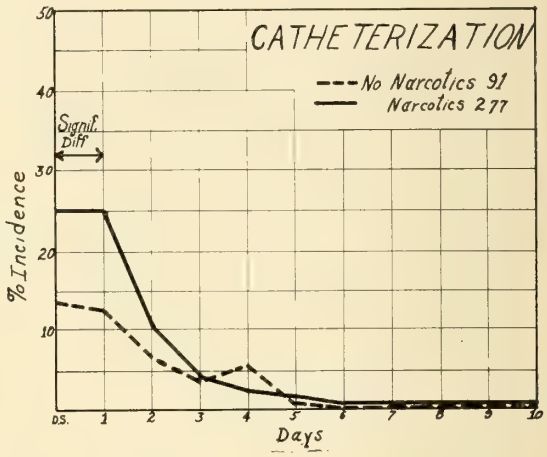

Fig. 8. The incidence of catheterization was significantly different only on the day of surgery.

is a variable effect depending upon the size of the dose,[13] and in all probability there are individual patient differences in sensitivity to the given dose. It is possible that even a single dose may set off the chain of events resulting in colic. The balance must be quite thin, for those receiving no morphine also had symptoms of gas pain, although not as many patients complained of this.

Incidence of Urinary Retention

The analysis of catheterizations indicates a statistically significant difference in the narcotic and no narcotic groups on the day of surgery and the first postoperative day (Figs. 8 and 9).

Urinary retention is most likely due to the spastic influence of morphine on the trigone musculature.[3,12] The morphine inhibition of water diuresis[3] may also play a part in the delay of urination.

Incidence of Emesis

The emetic property of opiate derivatives[12] on a sensitive individual is a well-known fact. In this study, emesis showed its greatest and only significant difference during the period of more frequent morphine administration, i.e., the day of surgery and first postoperative day (Figs. 10 and 11).

Other writers have noted other side effects of morphine which might affect the difference in morbidity found in this study. Hyperglycemia,[4] inactivation of cholinesterase,[23] decrease of prothrombin time,[14] as well as various cardiac, circulatory and metabolic changes,[7,20] have been observed and could influence postoperative morbidity.

To produce the true and complete relationship between the increased incidence of complications found by this clinical study and the pharmacological properties of morphine which might account for the increase, one must consider the factors common to both groups, name-

ly anesthesia, operation, and disease. The pharmacologic effects of morphine as related to these factors are likely quite different from normal or single factor situations.

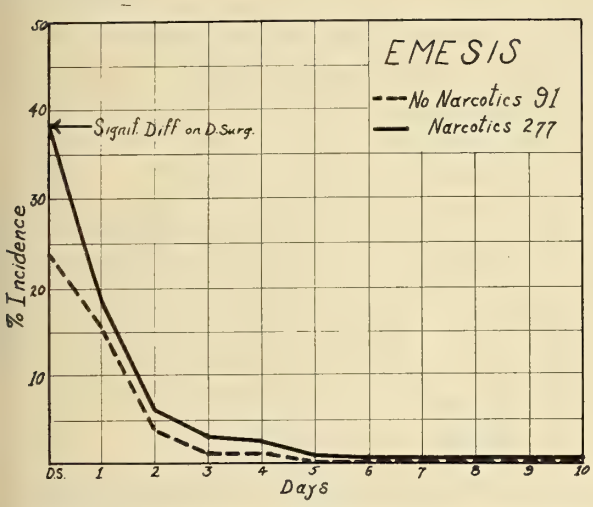

Fig. 10. Emesis occurred more frequently in the narcotic group only on the day of surgery. On that day a statistically significant difference appeared.

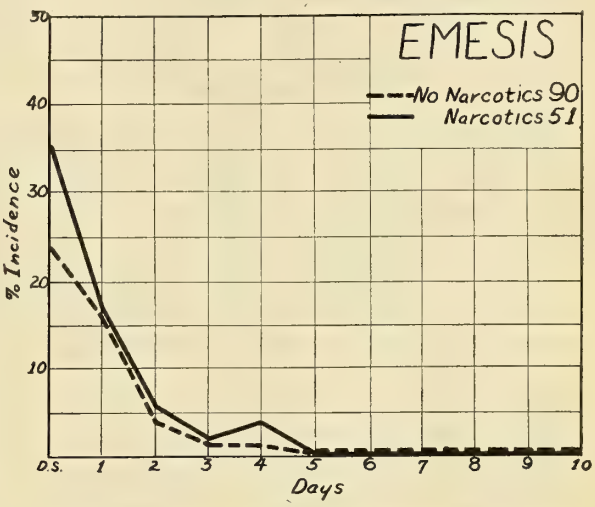

Fig. 11. Cases of Dr. X showing a similar curve to that in Figure 10.

Summary and Conclusions

A statistical evaluation of the influence of morphine on postoperative morbidity was made by comparing the incidence of complicating signs and symptoms between a group of ninety-one patients who received no morphine and a group of 277 patients who received varying doses of morphine.

A statistically significant difference was found in cough, gas pains, urinary retention, vomiting and fever in favor of the no-narcotic group.

The greatest difference was found to be cough, which was significant from the second through the tenth postoperative day.

The incidence of gas pain colic can be reduced by decreasing or eliminating the use of morphine.

Because of the undesirable side effects of narcotics, other methods or drugs for obtaining relief from pain must be searched for.

PREOPERATIVE AND POSTOPERATIVE NUTRITIONAL REQUIREMENTS

BURTON A. ORR, M.D., and CARL O. RICE, M.D., Ph.D.
Minneapolis, Minnesota

As one of the residents at the St. Barnabas hospital,

Dr. Orr is surgical resident at the St. Barnabas Hospital under the supervision of Carl O. Rice, M.D.

I have been assigned a problem dealing with preoperative and postoperative nutritional requirements. Dr. Strickler has presented some comparative morbidity figures which he obtained at the St. Barnabas Hospital about a year ago. He has also mentioned some nitrogen balance studies which evolved from his work at that time. These I have inherited.

Caloric Requirements

We have continued these investigations on the premise that the problem of maintaining the caloric requirement in the preoperative and postoperative periods must be faced. Before this could be done, some conception of the caloric requirement of the patient seemed necessary.

The basal caloric requirement may be established in several ways. The DuBois Charts[6] are simplest and are adequate for ordinary clinical purposes. It will be recalled that with the height and weight of the individual, the square meters of surface area can be read directly from the chart. The required calories per square meter for various age groups are noted on other charts. Therefore, the determination of calories required per square meter for the normal individual is a simple procedure. It has been the experience of Boothby[2] and others that estimations of this nature are usually correct within 10 per cent.

A more accurate means of determining the caloric needs is to establish the oxygen utilization rate with the aid of the usual basal metabolic rate apparatus. With this method, the respiratory quotient is usually assumed to be approximately .84, or normal. This implies that the usual amount of each type of food is being burned. Then about .4825 would represent the required calories necessary to consume one liter of oxygen.

Even more precision may be obtained by calculating the nonprotein respiratory quotient. Then, with the Schuntz table, one can note both the exact caloric need and the quantitative analysis of the food types burned.[4] However, if one chooses to ignore this feature, the error in caloric determination is pointed out by Magnus-Levy to be not in excess of 3 per cent.[8]

For the purpose of these studies we have not routinely determined the respiratory quotient, though we did so in a few instances when alcohol was being used as the principal source of energy. Low respiratory quotients were found in such instances. High values were found when carbohydrate was the principal source of energy. We expect to investigate this aspect further and more accurately with the idea of establishing a quantitative utilization of alcohol.

We obtained a routine basal metabolic rate on the patient the morning after admission to the hospital. This method of determining the calories, for the sake of these investigative studies, should be more accurate than the estimations from the DuBois chart of normals and will automatically correct for any caloric changes due to illness. With the oxygen utilization rate known, the twenty-four-hour basal caloric requirements may be calculated:

$$\frac{(1440 \text{ minutes in 24 hours})}{T \text{ (time of this test)}} \times 4.825$$

(calories in 1 L. O_2) = Total 24-hour heat output.

TABLE I. CALCULATION OF THE CALORIC REQUIREMENT

Case	H. H.	E. J.	W. C.
Degrees Rise in Fever	1.4	1	3
Fever Requirement (8%/Deg.)	182	123	444
SDA (8%)	130	123	148
Bed Activity (30%)	490	463	556
*Basal Caloric Requirements	1635	1544	1853
TOTAL CALORIC REQUIREMENT	2427	2253	3001
*Metabolic Rate (check)	2416	2422	2925

For each degree rise in temperature, 8 per cent of the basal caloric requirements must be added. The specific dynamic action (S.D.A.) requires an additional 8 per cent of the basal calories. Bed activity has been found to require approximately 30 per cent of the basal calories. The basal caloric requirements can be calculated as indicated in the text, or actually determined on the Jones Metabolic Unit. The sum of these values represents the total caloric requirements of the individual. To determine whether or not this calculation is correct, a metabolic rate check made with the Jones Metabolic Unit can be done. In each of these cases it can be observed that the metabolic check has been accurate within 10 per cent.

*Determined on a Jones Metabolic Unit.

From this formula the daily metabolic requirements are calculated as indicated in Table I.

If the basal caloric requirement is assumed to be the same each day, then we attempt to add the other caloric requirements for the somewhat fluctuant state of the patient incident to his illness. The specific dynamic action requires an addition of between 6 to 8 per cent of the basal calories when mixed dietary elements are being utilized.[11]

The activity requirement is certainly variable, but in the usual hospital patient we have been using figures up to 30 per cent of the basal caloric requirements. This additional caloric requirement is approximately the amount of energy utilized in being sick in bed, receiving medications, enemas, intravenous infusions and so forth, as is required to attend a patient in the hospital. The use of a kymogram for more accurate determination is being considered.

The requirement which changes most from day to day is that of fever. This requirement has been established at between 5 to 10 per cent for each degree rise in fever. We have been using 8 per cent. The sum total of such requirements should be about equivalent to the caloric needs of the patient. As a check on our calculations it has been interesting to measure the speed with which a liter of oxygen is consumed during activity, the burning of food (i.e. while an intravenous infusion is running), and while the patient has a fever. Those that we have done in this fashion have agreed essentially with our predetermined calculations. Three cases are illustrated in Table I where it can be observed that our predetermined total requirements were similar to the Jones M.R. check.

In an effort to determine the effect of an operation upon the metabolic rate, we have conducted a few preliminary tests directly before and within a short time after surgery. In the few cases which we have investigated there seems to be very little difference. A hint of elevation is suggested, as indicated in Table II.

Utilization of Ethyl Alcohol for Caloric Value

Having determined the caloric requirement, the next problem is that of meeting it. It is not unusual to find a requirement of 3,000 calories, or in some instances even more. In the belief that the patients should not be deprived of these calories during illness, needed even more than in health, we have endeavored to provide them directly after an operation.

The usual routine postoperative care provides the surgical patient with clear liquids during the first twenty-four or forty-eight hours. In this there are no calories, no protein, no carbohydrates. In our patients, immediate postoperative parenteral nutrition is commenced. The full caloric, carbohydrate and nitrogen requirements are provided. As soon as the patient is able to consume food by mouth, the parenteral feedings are diminished, taking care to provide only that amount which cannot be consumed by mouth.

Since it seems rather well settled that ethyl alcohol can be utilized for energy and is high in caloric value, we have found it convenient to add it to our intravenous solutions.[12] The initial studies pertaining to the use of glucose, amino acids and alcohol, all in one solution, are to be published in a forthcoming issue of the *Journal-Lancet*.

There are various estimates as to the rate and amount of alcohol utilized by the body. According to the work of Mellanby, 10 cubic centimeters an hour is considered to be the rate of utilization.[9] Exceedingly small quantities are excreted in the urine, expired gases and other bodily secretions. This total is probably not more than 2 per cent but may increase if the dose is excessive. The established caloric value of alcohol is set at 5.6 calories per cubic centimeter as noted in Goodman and Gilman.[7]

Sixty cubic centimeters of alcohol per liter of solution has been selected for routine use in our patients. This provides 336 calories. This is added to a bottle of commercially prepared Aminosol with 5 per cent dextrose solution. This solution includes 50 grams of the essential amino acids, representing 200 calories, and 50 grams of dextrose, also representing 200 calories. The addition of alcohol provides, therefore, 736 calories per liter. Amigen has also been used, especially when sodium chloride is desired. It provides slightly less protein.

These solutions have been used in more than 400 patients without ill effect. When a greater caloric intake was desired, we have increased both the alcohol and the dextrose with no undesirable effects. Four hours is the usual time required for administration.

TABLE II. PREOPERATIVE AND POSTOPERATIVE BMR COMPARISONS

Patient	BMR (Preoperative)			BMR (Postoperative)		
	O_2 Rate (Min.)	Calories	Date	O_2 Rate (Min.)	Calories	Date

* Temperature 100.2°
** Temperature 99.8°

A vein in the forearm or leg is used in preference to the antecubital vein in order to eliminate fatigue incident to keeping the arm extended upon a board.

Blood alcohol levels have been determined during the course of administration, and an attempt has been made to correlate the clinical manifestations. We have observed these patients passing through several clinical phases as the rate of administration is increased. Mild sedation and mild analgesia are observed first. Then the patient passes into a state of restlessness, but as the rate of administration continues, and presumably as the concentration in the blood increases, a soporific effect is manifest. Blood alcohol levels have been obtained after the method of Bodansky and Cavett.[5] Ten miscellaneous patients receiving routine Aminosol, glucose and alcohol showed a similar graphic picture.

TABLE III. SCALE OF TOXIC SYMPTOMS WITH VARIOUS BLOOD ALCOHOL LEVELS
(Modified from Miles[10])

Per Cent Alcohol in Blood	*Symptoms*
0.010	Head clearing. Freer breathing. Mild tingling.
0.020	Slight fulness and mild throbbing at back of head. Touch of dizziness. Fatigue relief. Tone of pleasantness.
0.030	Mild euphoria. No sense of worry.
0.040	Lots of energy for things he wants to do. Talks much and loudly. Hands tremble slightly. Clumsy. Not embarrassed. Glib and flippant remarks.
0.050	Normal inhibitions practically cut off. Long winded. Blunting of self-criticism.
0.070	Feelings of remoteness. Odd sensations on rubbing hands together or of touching of face. Rapid strong pulse and breathing. Amused at own clumsiness. Upsets chair on rising.
0.100	Staggers very perceptibly. Talks to himself. Difficulty clothing himself. Fumbling of keys. Feels drowsy, sings loudly.
0.200	Needs help to walk or undress. Easily angered. Shouts, groans, weeps by turns. Is nauseated. Poor control of urination.
0.300	In stuporous condition. Very heavy breathing. Sleeping and vomiting by turns. No comprehension of language. Strikes wildly at person trying to assist.
0.400	Deep anesthesia, may be fatal.

When the rate of alcohol administration was purposely maintained close to 15 cubic centimeters per hour:

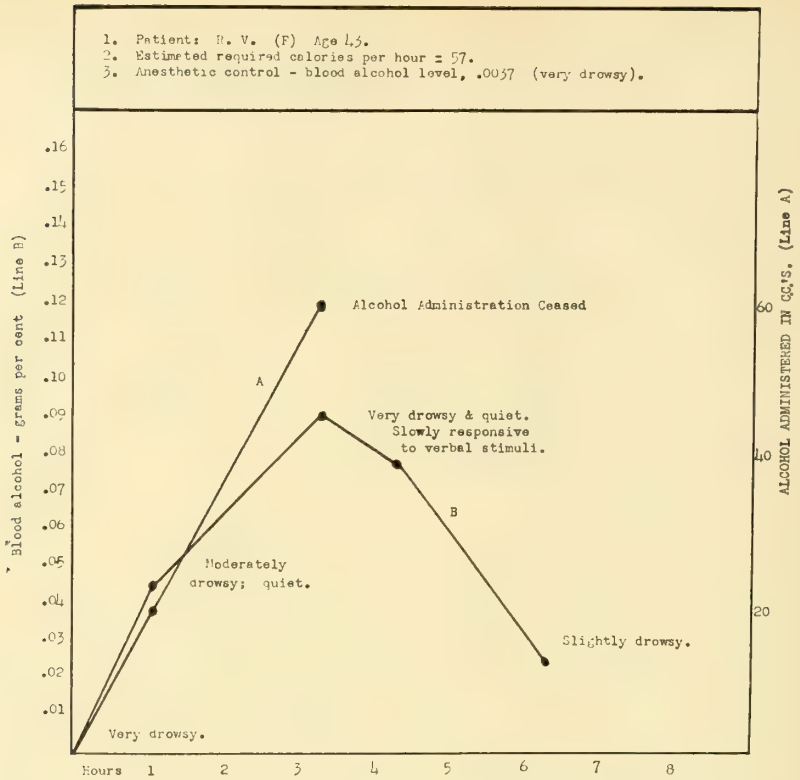

Fig. 1. The blood alcohol levels resulting from the administration of 60 c.c. of ethyl alchohol intravenously.

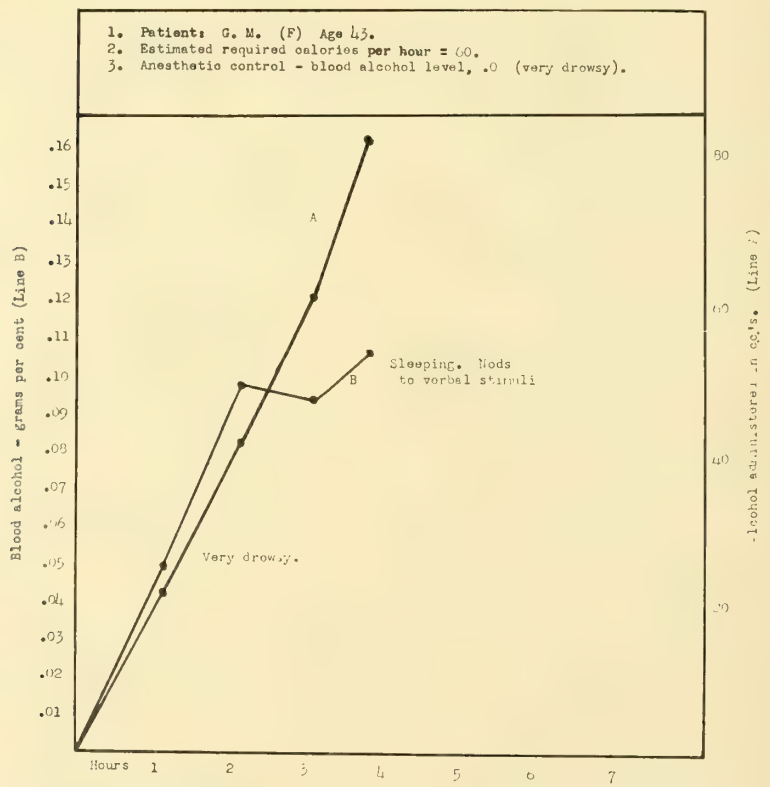

Fig. 2. The blood alcohol levels resulting from the administration of 80 c.c. of ethyl alcohol intravenously.

TABLE IV. PATIENT P. K., MALE, AGED FIFTY-FOUR

Weight 117 pounds (53 kilo.).
Estimated metabolic requirement 1873
Protein requirement @ 1 gm./kilo. = 53 gm.**
N_2 requirement @ 0.4 gm./kilo. = 21**

Date	9-26-47	27	28	29	30	10-1-47	2	3	4	5	6
Total Calories	2208	2208	2208	2208	1595*	2658*	2658*	1020			
Grams Protein	150	150	150	150	83.7	171.2	171.2	158.7			
% Calories from Protein	25	25	25	25	21	24	24	62

Urine Creatinine	2.3	2.9	2.5	2.7	2.6	lost	1.4	2.6			
Blood Protein	6.7									6.2	

* 500 c.c. of citrated whole blood contributed to these calories, protein and nitrogen intake.
It will be noted a strong positive nitrogen balance was maintained when the intake was 2208 calories the first 4 days. On 10-3-47 it was negative with low total calories and very high protein per cent.
** Though they do not coincide, both of these requirements have been cited in the medical literature.

1. The grams per cent of alcohol rose rapidly, leveling off in approximately two hours.

2. The levels seemed to vary with the size of the patient. We are endeavoring to correlate the utilization of alcohol with the caloric requirement.

3. The average concentration after attaining a level at this rate of administration was approximately .05 grams per cent.

4. These low levels tend to remain effective in producing adequate sedation for several hours after discontinuing, for ordinary purposes.

5. If the administration rate is similar to the utilization rate, the levels tend to remain constant.

Table III, copied from Goodman and Gilman, indicates the symptoms from increasing blood alcohol levels.

In the alcohol blood levels of approximately 0.1 to 0.15, the patient seems distinctly depressed, particularly if associated with sodium luminal. This combination has seemed rather satisfactory for pain relief. In the lower blood alcohol level range, it has been necessary to occasionally use sodium salicylate in order to obtain relief of pain.

Figures 1 and 2 illustrate the administration of alcohol on a caloric basis. Sufficient calories are offered in three hours to cover the basal needs for 5.6 hours. The peak levels here seem desirable for the immediate postoperative period. In Figure 2 we note a secondary rise when the rate is increased.

It will be observed that the range of blood alcohol level is lower than the average intoxication level and far indeed from the lethal level. Recently we have found that higher levels might be indicated to afford more pain relief on the first postoperative day. The rate of drip of this solution must be regulated lest too rapid infusion of amino acids produce nausea and vomiting. In raising the blood alcohol levels higher, we have, therefore, chosen to add more alcohol to the Aminosol or to administer more rapidly solutions of lower alcohol percentage.

Utilization of Amino Acids for Nitrogen Metabolism

One liter of 5 per cent Aminosol provides the equivalent of 50 grams of utilizable protein having a nitrogen value of 8 grams. We have conducted nitrogen balance studies and have demonstrated repeatedly the ability of the body to maintain a stron gpositive nitrogen balance with 2,000 or 3,000 cubic centimeters of glucose, Aminosol and alcohol (each 5 per cent). Three liters of this solution provides 2,208 calories and 24 grams of nitrogen. Nitrogen requirement has been established by other investigators as 4 grams per kilogram. A 154-pound man (70 kilograms) would then require 28 grams of nitrogen.[1]

Variations in the carbohydrate, amino acids and calories (as provided by alcohol) have clearly demonstrated to us that a strong positive nitrogen balance is difficult to maintain unless adequate calories are available, even though the nitrogen intake exceeds considerably the normal requirements. Nitrogen equilibrium may be obtained with a relatively low caloric intake and normal nitrogen intake, but that does not allow much opportunity for rebuilding of nitrogen-containing tissues. Healing tissues require abundant nitrogen, and in order that this may obtain, a strong positive nitrogen balance must be evident.

Some of the above observations are illustrated in Table IV, where it will be observed that a strong positive nitrogen balance was maintained when the caloric intake was 2,208 as indicated for the dates September 26, 27, 28, and 29. On September 3, 1947, a negative nitrogen balance resulted when total calories were insufficient though the percentage of calories derived from protein and the grams of protein were both increased above the usual physiologic requirements.

The study of other protocols led us to believe that, presuming the caloric intake to be sufficient, approximately 25 or 30 per cent of the calories derived from protein provide optimum physiologic economy. In other words, if the normal amount of nitrogen is provided and protected with added glucose and calories, a relatively low nitrogen quantity is excreted and a high positive nitrogen balance is obtained. The retained nitrogen can be utilized for tissue repair. It is important that a strong positive nitrogen balance be maintained during the healing phase of any disease. Cannon,[3] in the *Journal of the American Medical Association* has pointed out on the basis of his experimental studies that "tissue synthesis requires enough calories to facilitate the conversion of amino acids into tissue protein, but above a certain level additional calories are superfluous." Our studies have been leading us to the same conclusion.

Utilization of Glucose

It is not necessary to discuss the utilization of glucose at this time, as these studies are adequately dealt with in the medical literature. It is well to recall, however, that glucose is essential for the proper metabolism of carbohydrate, and proteins, without which protein must be utilized to provide a deficiency of glucose before it can be used for tissue repair. If given slowly, glucose can be consumed in greater quantities than it is practical to administer. Woodyatt demonstrated that, if given slowly, .9 gram per kilogram per hour could be utilized by the normal body for an indefinite interval.[1] It can be administered in 10 per cent concentrations for short periods of time and in 7.5 per cent concentration for longer periods of time without producing thrombosis of the vein.[3] At the rate at which we have administered it (5 per cent—7.5 per cent—10 per cent) we have noticed no appreciable loss of glucose through the urine. A 5 per cent solution administered over four hours provides approximately .2 gram per kilogram per hour for a 150-pound man.

Comments

Our clinical observations suggest that by maintenance of full caloric and nutrional need, smoother convalescence and a more rapid feeling of well-being is obtained than when the patient is placed on a routine postoperative, clear, liquid, soft, light and full diet.

Vitamin C and the B complex factors are administered when oral nutrition is inadequate. Experimental studies have shown rapid depletion of these vitamins when they are not obtained in a daily diet. Experiments have also shown the importance of these vitamins in protein metabolism and wound healing.

These studies are still somewhat in the nature of a preliminary report, in that we have not yet carried out these investigative studies on enough individual cases. However, our clinical observations have been adequately convincing so that we feel free in recommending this method of preoperative and postoperative nutrition for all patients who must otherwise suffer the effects of semistarvation for a week or 10 days.

THE RATIONALE OF ELIMINATING STARVATION POSTOPERATIVELY

CARL O. RICE, M.D., Ph.D., J. H. STRICKLER, M.D., and BURTON A. ORR, M.D.
Minneapolis, Minnesota

Dr. Strickler has indicated a statistically significant difference in the incidence of a certain number of postoperative complications and sequelae. He has indicated that morphine has contributed to some of such sequelae. On this basis we have undertaken some special studies relative to the mechanism of gas pain colic.

Preoperative and postoperative flat roentgenograms of the abdomen revealed gas in both the small and large bowels within a few hours after operation, whereas it was not evident before operation. This finding was constant in all cases whether the patient had received morphine or not.

In the morphine group we found areas of segmental spasm in the colon in eight out of ten cases. In the no-morphine group there were no segmental spasms.

We then checked with scout films a number of patients presenting gas pain colic, some of which were included in the above 10 cases, and in these we found segmental spasm.

Benzedrine sulphate, 10 milligrams, was administered to patients with gas pain colic and within a few minutes the segmental spasm disappeared. Gas pain colic was relieved and the gas was rapidly dissipated. This suggested to us that gas pain colic involved a mechanism wherein an area of segmental spasm develops, upon which is superimposed a peristaltic rush. Morphine, because of its tendency to increase the tone of the bowel, also may produce areas of segmental spasm, thereby contributing to the increased incidence of gas pain colic. Benzedrine has therefore been used to relieve gas pain colic. Gas pain colic and gas distention must be differentiated.

In an effort to provide a substitute for morphine to relieve postoperative discomfort, we used intravenous alcohol. In the past eight or ten months we also have provided glucose and amino acids, each for its nutritional and caloric value. This led to a study of nitrogen balance.

Dr. Orr has described some of the investigations we have undertaken at St. Barnabas Hospital pertaining to preoperative and postoperative nutrition, and he also has described the technique of administration of glucose, amino acids and alcohol. Some of this still is in the nature of a preliminary report. Further substantiation will be needed. However, these data have helped us form opinions, and we believe we are justified in recommending them to you even at this early stage.

Physiologic Properties and Nutritional Values of Alcohol

Alcohol provides sedation and calories. The determination of alcohol levels of the blood, in association

This discussion, based on investigative studies made at the St. Barnabas hospital, has been made possible through the generosity of the hospital board, the hospital administration and the professional personnel, all of whom have contributed cheerfully of their encouragement, money or effort.

TABLE I

Period	I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII	XIII	XIV	XV	XVI
Av. Total Calorie Intake per day	2646	2501	3207	1936	1392	1996	2969	3108	2116	432	2178	1629	2333	1748	2181	2208
Av. Calories from Protein	369	362	472	294	240	362	570	600	400	87.6	420	368	521	443	560	600
% Calories from Protein	13.9%	14.4%	14%	15%	17%	18%	19%	19%	19.8%	20.3%	20%	22.5%	22.3%	25%	25%	27%
Av. Nitrogen Intake in grams	14.66	14.45	18.9	12.4	9.6	14.5	22.4	24	16	3.5	16.9	14.7	20.9	17.8	22.4	24
Av. Nitrogen Output in grams	12.77	12.16	4.5	19.48	9.9	10.8	14.2	11.77	12.6	11.1	9.3	9.6	15.1	14.5	6.1	11.46
Nitrogen Balance	+1.89	+2.29	+14.4	−7.58	−.3	+3.7	+8.2	+12.23	+3.4	−7.6	+7.6	+5.1	+5.8	+3.3	+16.3	12.54
Temperature	99.7°	101.4°	101.8°	100.8°	100.6°	100°	102.8°	101.4°	101°	102.2°	100°	101.8°	102.6°	101.6°	101.6°	102.4°
Calculated caloric requirement—2071																

Male, aged fifty-nine, weight 71 kilograms. Each period represents either two or three days in which the caloric and protein intake were similar. The figures represent the average values, nitrogen balance studies having been made every day.

with subjective symptoms and objective findings, suggests that the first effect of alcohol is mild sedation, obtained when the blood level reachs .04 to .08 grams per cent. In most instances this is sufficient to relieve the patient of the immediate postoperative distress.

After the patient returns to his bed from the operating room and is still semiconscious, he is given his initial intravenous glucose, amino acids and alcohol. In some instances we eliminate the amino acids from the initial dose, because of its tendency to produce nausea in a patient who already is nauseated from his anesthetic.

The rate of administration is increased for the first twenty or thirty minutes so that the patient receives approximately 15 or 20 cubic centimeters of alcohol during this period. This is done with the idea of promoting sedation. Thereafter, the rate of administration is decreased and maintained at a constant rate throughout a full four-hour period.

Most patients obtain sufficient sedation and analgesia from this rate of administration. A few have received intravenous sodium salicylate in addition, so as to obtain the synergistic effect of alcohol and salicylate.

We are interested in sedation and analgesia for only the first twelve or twenty-four hour period. Thereafter, patients rarely require additional analgesia.

After sedation has been obtained, we then are interested in this solution for its nutritional value. Alcohol provides approximately 6 calories per cubic centimeter of immediate energy. It thereby spares reserve stores of carbohydrate and protein. Alcohol is metabolized at the rate of approximately 10 cubic centimeters an hour. Only a small quantity is excreted unchanged. The excess, if it is given too rapidly, is held in the blood stream and the tissues and, depending upon its concentration, may produce sedation, analgesia, narcosis, intoxication, stupor and death. The sedative and analgesic, narcotic and intoxicating dose is sufficiently far removed from the lethal dose to make it safe for therapeutic purposes.

Alcohol increases capillary dilatation. It is said to act as an antispasmodic in the gastrointestinal tract, contributing thereby to the elimination of segmental spasm and gas pain colic. It has been used clinically for its beneficial effects upon peritonitis and paralytic ileus. It increases the depth of respiration, thereby contributing to eliminate pulmonary complications. It promotes mild diuresis. It causes no significant change in the blood pressure or pulse.

The undesirable effects of alcohol, namely intoxication, stupor and death, are easily avoided clinically by controlling the rate of administration. Its intravenous administration produces no "hang-over" symptoms.

With these desirable features of alcohol as a physiologic drug and a source of easy energy, we have used it routinely in all our patients postoperatively with the above thought in mind.

Nutritional Value of Amino Acids

Numerous investigations have demonstrated recently the value of maintaining a positive nitrogen balance in the sick individual, both preoperatively and postoperatively. A high protein, adequate calorie diet is the first requisite in this regard. It has been noted repeatedly in medical literature that the difficulty in maintaining adequate nutrition in the individual who cannot eat is that of providing sufficient calories without, at the same time, providing too much fluid.

Six thousand cubic centimeters of fluid are needed to provide 2,400 calories, using 5 per cent glucose and 5 per cent amino acids. Increasing the concentrations of glucose and amino acids to decrease the fluid content results in undesirable sequelae: thrombosis from high concentrations of glucose; nausea, flushing, giddiness from greater concentrations of amino acids. By adding alcohol to the glucose-amino acids solution, caloric value can be doubled almost. In this manner a patient can be given his full caloric, nitrogen and glucose requirements in 3,000 cubic centimeters or less of intravenous solution.

I am not convinced that forced or tube feedings can provide these nutritional requirements any better than can be done by our intravenous method.

Dr. Orr has demonstrated the protocol of a patient in whom nitrogen balance studies were conducted, pointing out the need for providing sufficient calories in order to maintain a positive nitrogen balance.

I should like to emphasize the need of providing also an adequate percentage of calories derived from protein as indicated in the protocol of a man, aged fifty-nine, of 71 kilograms weight, who suffered from carcinoma of the colon (Table I). He was provided with adequate calories and at least 1 gram of protein per kilogram body weight. In periods I and II, where approximately 14 per cent of the calories were derived from proteins, he was barely in nitrogen balance, and, as in period IV, when the total calories were decreased, he showed a negative nitrogen balance, even though the grams of protein were adequate and the percentage of nitrogen slightly higher. In period III where the percentage of protein was kept the same while the calories were in-

creased, a strong positive nitrogen balance developed. Comparing this with period VIII, in which the calories were kept essentially the same but the percentage of protein was increased, a strong positive nitrogen balance still developed. If the calories are again decreased, though the protein percentage continues to remain high, the nitrogen balance also decreases, as indicated by comparing period VIII with periods IX and XIV.

It will be noted that when the caloric intake dropped below the calculated caloric requirement (2071C), the patient was in negative nitrogen balance, as indicated in periods IV, V and X.

In periods VI and XII, the caloric intake was inadequate, but the protein intake was high. In these two periods, the patient was barely in positive nitrogen balance. When these two periods are compared with periods III, XV and XVI, in which both the calories and protein were high, it is noted that a strong positive nitrogen balance developed.
